## ACKNOWLEDGMENT

I sincerely thank to my advisor Assoc. Prof. Dr. Ferda SOYER for giving me the opportunity to work in her laboratory as well as her support and patience during the years of my Masters and PhD studies. I feel honored to be improved in science and life by her dependable guide and invaluable experiences which will lead me throughout my life. I wish to thank Assoc. Prof. Dr. Gülistan MEŞE ÖZÇİVİCİ and Assist. Prof. Dr. Nur Başak SÜRMELE for being in my thesis supervising committee and their invaluable advices on the development of my PhD studies. I want to thank Assist. Prof. Dr. Ayşe Banu DEMİR and Assist. Prof. Dr. Yavuz OKTAY for being my PhD defense committee members. I am thankful to Prof. Dr. Talat YALÇIN for his kindness to allow me to use his laboratory facilities and his valuable help during my proteomics studies. I am also grateful to Assoc. Prof. Dr. Özden YALÇIN ÖZUYSAL for her kind help and invaluable guide in my RT-qPCR studies as well as allowing me to use her laboratory facility in c-DNA preparation step. In addition, I thank to Dr. Melike DİNÇ and Burcu FIRATLIGİL YILDIRIR for their valuable assistance in my proteomics and c-DNA preparation studies, respectively. I would also like to thank Özlem ECE for her kind help and assistance in my scanning electron microscopy studies.

I genuinely thank to my dear friend Dr. Deniz KEMAN for being not only a good labmate but also being one of my best friends. During the years we worked together I found out her intelligent, hard-working, supportive, humorous and sincere character, and I feel so lucky to have such a wonderful person in my life. I also wish to thank Ertuğrul ACAR for being such a good labmate and for his sincere and valuable friendship.

I wish to express my sincere gratitude to my dear family: my father Namık Kemal ÖZDEMİR, my mother Embiye ÖZDEMİR and my brother Seçkin Ozan ÖZDEMİR. They are always a loving family who supports me under every circumstance. I am very grateful for their limitless love and patience towards me as well as enormous mental and material supports throughout my life, especially in my PhD study period. I feel as I am the luckiest person for having such a wonderful family.

## ABSTRACT

### MOLECULAR INVESTIGATION OF PATHOGENIC BACTERIA IN THE PRESENCE OF PHENOLIC ACIDS

Pathogenic bacteria, including *P. aeruginosa*, are serious threats for human health with their antibiotic resistance and virulence factors. Since phenolic acids, secondary metabolites of plants, can be good candidates as antimicrobial agents, their mode of action should be investigated. Proteomics is one of the main approaches for elucidating the mode of action of such compounds. In addition, in order to enhance the antimicrobial effects and stabilities of phenolics, they can be encapsulated into nanoparticles. The nanoparticles can be produced from chitosan and alginate which are biocompatible polymers. In this study, the antimicrobial effects of 3-HPAA and 4-HBA were presented with MIC values of 2.1 and 1.9 mg/ml, respectively. The bacteriocidal effects of them were also shown as 2.3 mg/ml for 3-HPAA and 2.1 mg/ml for 4-HBA. The morphological changes of bacteria were determined after phenolic acid exposure via SEM. The LC-ESI-MS/MS technique was used to show changes in the protein profile of bacteria arose from antimicrobial effects. Both phenolic exposures resulted in various protein changes especially in membrane-related proteins as well as ribosome and protein synthesis related-proteins. In addition, they caused serious oxidative stress depending on the protein profile changes related to redox proteins. Alginate-chitosan nanoparticles resulted increased antimicrobial effects of the phenolics which were produced, characterized and tested on various pathogenic bacteria via agar diffusion and spectrophotometric measurements. Hence, free or encapsulated forms of phenolic acids were demonstrated as effective antimicrobial agents and based on proteomic results, the effect of phenolic acids may be multi targeted.

## ÖZET

### FENOLİK ASİTLERİN VARLIĞINDA PATOJEN BAKTERİLERİN MOLEKÜLER İNCELEMESİ

*P. aeruginosa*'nın da içinde bulunduğu patojen bakteriler antibiyotik dirençlilikleri ve virülans faktörleri nedeniyle insan sağlığı için önemli bir tehdit oluşturmaktadır. Bitkilerin sekonder metabolitleri olan fenolik asitler antimikrobiyal madde olmak için iyi adaylar olduklarından, etki mekanizmalarının çalışılması gereklidir. Proteomik çalışmalar, böyle maddelerin etki mekanizmalarının araştırılmasındaki önemli yaklaşımlardan biridir. Bunun yanısıra, kararlılıklarının ve antimikrobiyal etkilerinin artırılması için, fenolik asitler nanopartiküller içerisine hapsedilebilirler. Nanopartiküller, biyo-uyumlu polimerler olan kitosan ve aljinattan sentezlenebilirler. Bu çalışmada, 3-HPAA ve 4-HBA'nın antimikrobiyal etkileri, sırasıyla 2.1 and 1.9 mg/ml olan minimum inhibe edici konsantrasyon değerleri ile sunulmuştur. Aynı zamanda bakterisidal etkiye sahip oldukları ise 3-HPAA için 2.3 mg/ml ve 4-HBA için 2.1 mg/ml minimum bakterisidal konsantrasyon değerleri ile gösterilmiştir. Buna ek olarak, bakterilerin morfolojilerinde fenolik asit uygulamasından sonra oluşan değişiklikler de taramalı elektron mikroskobu ile tespit edilmiştir. LC-ESI-MS/MS tekniği, antimikrobiyal etkiler nedeniyle protein profilinde oluşan değişiklikleri göstermek için kullanılmıştır. İki fenolik muamelesi de bakterinin protein profilinde, zarla ilgili proteinlerdeki, ribozom ve protein senteziyle ilgili proteinlerdeki değişimler başta olmak üzere, birçok değişime neden olmuştur. Bunun yanında, redox proteinlerindeki değişimler göz önüne alındığında, fenoliklerin bakterilerde ciddi oksidatif strese yol açtığı görülmüştür. Fenolik asitlerin enkapsüle edilmesini sağlayan, sentezlenen, tanımlanan ve antimikrobiyal etkileri birçok patojen bakteride agar difüzyon ve spektrofotometrik ölçümlerle test edilen aljinat-kitosan nanopartiküller ise, fenoliklerin antimikrobiyal etkilerinin artmasını sağlamıştır. Bu çalışmayla fenolik asitlerin hem serbest, hem de enkapsüle edilmiş hallerinin etkili antimikrobiyal maddeler oldukları sunulmuş ve proteomik çalışmanın sonuçlarına göre fenolik asitlerin çoklu-hedefli etkiler gösteriyor olabildikleri sonucuna varılmıştır.

*This thesis is lovingly dedicated to my dear family.*

## LIST OF ABBREVIATIONS

ACN	Acetonitrile
Alg-Chi	Unloaded alginate-chitosan nanoparticles (null nanoparticles)
BER	Base excision repair
BSA	Bovine serum albumin
CaCl <sub>2</sub>	Calcium chloride
cfu	Colony forming unit
ddH <sub>2</sub> O	Double-distilled water
DLS	Dynamic Light Scattering
ESI	Electrospray ionization
FA	Formic acid
FT-IR	Fourier Transform Infrared Spectrometry
g	Gram
h	Hours
HCl	Hydrochloric acid
HPLC	High pressure liquid chromatography
ICU	Intensive care units
LC	Liquid chromatography
LC-ESI-MS/MS	Liquid chromatography-electrospray ionization-tandem mass spectrometry
MBC	Minimum bacteriocidal concentration
MDR	Multidrug-resistant
MHB	Mueller Hinton broth
MHA	Mueller Hinton agar
MIC	Minimum inhibitory concentration
MRSA	Methicillin resistant <i>Staphylococcus aureus</i>
MSSA	Methicillin sensitive <i>Staphylococcus aureus</i>
MMR	Mismatch repair
M	Molar
mM	Milimolar
μl	Microliter

ml	Mililiter
mg	Miligram
NaOH	Sodium hydroxide
NER	Nucleotide excision repair
nm	Nanometer
O.D.	Optical density
OOWW	Olive oil waste water
PDI	Polydispersity index
RP	Reversed-phase
RT-qPCR	Real Time-Quantitative Polymerase Chain Reaction
ROS	Reactive oxygen species
SEM	Scanning Electron Microscopy
SCX	Strong cation exchange
SSC	Staphylococcal cassette chromosome
STRING	Search Tool for the Retrieval of Interacting Genes/Proteins
TSA	Tyrptic soy agar
T6SS	Type VI secretion system
v/v	Volume/Volume
WHO	World Health Organization
XDR	Extensively drug-resistant
x g	Gravity
3-HPAA	3-hydroxyphenylacetic acid
3-HPAA-Alg-Chi	Alginate chitosan nanoparticles loaded with 3-HPAA
4-HBA	4-hydroxybenzoic acid
4-HBA-Alg-Chi	Alginate chitosan nanoparticles loaded with 4-HBA

# CHAPTER 1

## LITERATURE REVIEW

### 1.1. Scope of the Study

Throughout the history, the human well-being is threatened by various diseases in which the bacterial infections cover a huge part. The bacterial infections arise from the pathogenic, opportunistic bacteria, which result in high mortality and morbidity as well as reduced life quality and high economic costs. Even today the bacteria still continue to cause various infections that are attempted to be controlled. The most effective way to combat these infections is using antimicrobial agents, specifically antibiotics, since the starting of usage of them lead a decline in these infections, worldwide. From the introduction of antibiotics for clinical use such as sulphonamides in 1935, penicillin in 1941, streptomycin in 1943 and many others since, the rapid decrease in these infections are reported (Aminov, 2017) which covers the duration of the discovery, development and use of the antibiotics between 1940-1970 (the golden age of antimicrobial therapy) (De Mol et al., 2018). However, the increased usage of the antibiotics in humans and animals are also result in the resistance development of the pathogenic bacteria since 20th century, which is still a serious problem (Caffrey et al., 2019). This is also presented by the important international agencies like World Health Organization (WHO) and the European Centre for Disease Prevention and Control (<https://www.who.int/en/news-room/fact-sheets/detail/antibiotic-resistance>, Access date: 06.04.2019; <https://www.ecdc.europa.eu/en/publications-data/surveillance-antimicrobial-resistance-europe-2017>, Access date: 06.04.2019). Various pathogenic bacteria are turn out to be multidrug-resistant (MDR) and even, extensively drug-resistant (XDR) bacteria (Durand et al., 2019). Thus, this period can be accepted as the post-antibiotic era (Murima et al., 2014). This situation shows that the continuation in antibiotics usage may result in elevated and formidable bacterial infections. It is assumed that by the year of 2050, the infections will globally cause ten million deaths per year (Maldonado-Carmona et al., 2019). In addition to the antibiotics resistance, the bacteria possess various other virulence factors to develop and maintain infections such

as biofilm formation and secretion of toxic substances (Bleves et al., 2010). Even in the hospitals, during the treatment of diseases such as in the cancer treatment (Galloway-Pena et al., 2017) or surgeries such as in the implant replacements (Zhou et al., 2015), these bacteria are the main reasons of the nosocomial infections. Infections that arise from food-borne pathogens also cause serious diseases and outbreaks, worldwide. Hence, in addition to development of new designs of existing antibiotics (Lewis, 2017), brand new antimicrobial agents and new routes for treatment of the bacterial infections are globally investigated.

Bioactive compounds such as phenolics, which are found naturally in almost all plants, are accepted as one of the promising agents for antimicrobial therapy. These compounds demonstrate a bacteriostatic effect through inhibition of bacterial growth or a bacteriocidal effect by killing the bacteria in a dose-dependent manner. However, the molecular basis of their antimicrobial effect must be investigated by –omics studies, such as changes at the proteomic level, in order to use them as new antimicrobial agents (Maldonado-Carmano et al., 2019). Additionally, since the encapsulation of these agents into nanoparticles can enhance and/or elongate the stability of their antimicrobial properties, it is considered as an important method for maintenance of antimicrobial activity.

Figure 1.1. The chemical structures of phenolic acids focused in this study. a) 3-HPAA  
b) 4-HBA (Sources: Sigma-Aldrich)

The scope of our study covers the demonstration of water-soluble, simple phenolic acids with their high antimicrobial effects on *Pseudomonas aeruginosa* which is one of the most important pathogenic bacteria, as well as the proteomic changes in the protein profile of this bacteria to enlighten the action path of these agents. In addition, our scope

also covers the presentation of the antimicrobial effects and possible application route of the phenolic acids on various pathogenic bacteria *in vitro* after the encapsulation into alginate-chitosan nanoparticles.

## 1.2. Pathogenic Bacteria

The pathogenic bacteria, which are the causes of serious infections worldwide, were examined in this study for testing new antimicrobial agents. Among these, the well-known nosocomial pathogen, *Pseudomonas aeruginosa* was in the focus of this study to enlighten the proteomic changes for determination of the possible targets of the phenolic acids as promising antimicrobial agents.

### 1.2.1. *Pseudomonas aeruginosa*

*Pseudomonas aeruginosa* is a Gram negative bacterium which can be colonized in various environments (i.e. soil and water), plant and animal tissues (Ha and O'Toole, 2015; Valentini et al., 2018) as well as instruments and surfaces of the hospitals (Huber et al., 2016). As widely distributed opportunistic pathogens (Brown et al., 2012), they are accepted as one of the most important pathogenic bacteria in nosocomial (hospital-acquired) infections, worldwide (Klockgether and Tümmler, 2017) as well as in the community-acquired infections (Driscoll et al., 2007). Such that, *P. aeruginosa* are counted in the ESKAPE pathogens which stands for they are among six highly antibiotic resistant bacteria that mainly cause nosocomial infections: *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa* and *Enterobacter* species (Murray et al., 2015). They take roles in serious infections such as pneumonia, meningitis, abscess, soft tissue infections, urinary tract infections and catheter associated infections (Chatterjee et al., 2016) as well as causing the infections that can result in deaths in immunocompromised individuals such as cancer, burn, HIV, cystic fibrosis and organ transplantation patients (Morita et al., 2014; Huber et al., 2016). *P. aeruginosa* may be the causative agent of both acute and chronic infections (Valentini et al., 2018). The important properties of *P. aeruginosa*, which show an extremely diverse genotype and phenotype (Silby et al., 2011; Huber et al., 2016), are the ability to adapt various environments via broad

changes in metabolism, possessing virulence factors such as proteases, lipopolysaccharides and exotoxins (Gellatly and Hancock, 2013) and to switching the life-style according to the conditions (Morita et al., 2014). The bacteria can be either in planktonic life-style by which causing acute infections or they can be in biofilm forming life-style which aids the attachment and continuation in chronic infections (Valentini et al., 2018). They also have the both intrinsic and adaptive resistance abilities against various antibiotics (Morita et al., 2014; Pang et al., 2019). This high resistance property may arise from the low permeability of outer membrane of *P. aeruginosa* against many antibiotics (Breidenstein et al., 2011). For instance, they have resistance to antibiotics in use such as penicillins, cephalosporins, carbapenems, monobactams and fluoroquinolones (Poole, 2011; Lister et al., 2009) which leads to the very limited therapeutic options for these bacteria. Since they are life-threatening pathogens with which to combat is highly challenging, it is required to discover, design and develop new antimicrobial agents and treatment routes against *P. aeruginosa*, urgently.

### **1.2.2. Other Pathogenic Bacteria**

The other pathogenic bacteria in this study are important nosocomial pathogens; *Staphylococcus epidermidis*, *Acinetobacter haemolyticus*, Methicillin resistant *Staphylococcus aureus* (MRSA) and Methicillin sensitive *Staphylococcus aureus* (MSSA) in addition to serious food-borne pathogens; *Salmonella* Enteritidis, *Escherichia coli* O157:H7 and *Listeria monocytogenes*.

*S. epidermidis* are Gram positive bacteria (Neely and Maley, 2000) and they are normal occupants of skin and mucous membrane flora of humans and other mammals (Parlet et al., 2019; Argudin et al., 2015). As opportunistic pathogens, they are accepted as the cause of various infections since 1970s with the important virulence factors of biofilm formation and antibiotics resistance (Piette and Verschraegen, 2009). Among these, the antibiotic resistance is a major problem to fight against Staphylococci with a 91% resistance in clinical samples (Argudin et al., 2015). It can be stated that all infections caused by *S. epidermidis* are persistent against treatments (Schoenfelder et al., 2010). *S. epidermidis* with antibiotics resistance are colonized in patients and in/on hospital devices/areas by which the infections of these organisms take place (Piette and

Verschraegen, 2009). These infections resulted in significant outcomes for morbidity, mortality and economic costs.

*S. aureus* are Gram positive bacteria which are the causative agents of various hospital-acquired and community-acquired infections (Bitrus et al., 2018). Methicillin resistant *S. aureus* (MRSA) and Methicillin sensitive *S. aureus* (MSSA) are known as the “hospital pathogens” and “superbugs” with their resistance against many antibiotics (Nordmann et al., 2007). They are one of the ESKAPE pathogens since being in the aforementioned six highly antibiotic resistant nosocomial bacteria (Murray et al., 2015). They may cause acute infections by secreting virulence factors such as exotoxins and hydrolytic enzymes or chronic infections such as osteomyelitis, rhino sinusitis and otitis (François et al., 2010). The bacteria can survive by adapting to the environmental conditions immediately, for instance, the methicillin resistance was detected after six months of the initial clinical usage of methicillin in 1961 (François et al., 2010). The possession of the mobile genetic element staphylococcal cassette chromosome (SSC) which contains the *mec* gene in their chromosome (SSCmec genomic island), which has a broad genetic diversity, *S. aureus* strains (especially MRSA) gain the high antibiotic resistance (Bitrus et al., 2018). That result in the limited choices for the treatment of the infections of *S. aureus* and new antimicrobial agents are in search worldwide.

*A. haemolyticus* are Gram-negative opportunistic bacteria which are found in soil and waste waters in addition to being a normal occupant of healthy human skin, throat and intestine (Mujumdar et al., 2014). *Acinetobacter* species are considered as nosocomial pathogens which can cause various infections such as urinary tract infections, wound and burn infections and pneumonia and they are important agents of nosocomial outbreaks (Bergogne-Berezin, 1995). *Acinetobacter* develop resistance against common antibiotics in use and the infections caused by these bacteria are related especially with intensive care units (ICU) patients (Tripathi et al., 2014).

*S. Enteritidis*, *E. coli* O157:H7 and *L. monocytogenes* are food-borne pathogenic bacteria (Alegbeleye et al., 2018) that can lead food-borne infections via food poisoning. Food-borne diseases arise from contaminated food or water consumption by the food-borne pathogens or their toxins (Heredia and Garcia, 2018; Cisse, 2019). They are serious threats for human health, cause serious illnesses including diarrhea which may lead outbreaks in or between countries with high mortality and morbidity worldwide, as well as causing high economic costs (Alegbeleye et al., 2018; Franz et

al., 2019; Heredia and Garcia, 2018). According to WHO report in 2015, one of the 10 people experience diseases of food poisoning every year and about 420,000 deaths were presented, worldwide (Alegbeleye et al., 2018). The report indicates that the food-borne diseases resulted in nearly 23 million illness cases among which 5000 deaths occurred every year in Europe (Flynn et al., 2019). Although the food safety maintenance bears a high importance to reduce food-borne illnesses, it is a challenging process because of the errors at food processing and consumer levels as well as at the microorganism level (Franz et al., 2019). The resistance development of the microorganisms against antimicrobial agents is one of the primary reasons of problems in food safety (Franz et al., 2019) and new antimicrobial agents must be developed for both protection and treatments of food-borne diseases.

### **1.3. Phenolic Acids**

The phenolic compounds, which are widely produced as secondary metabolites by almost all plants and fungi, are the phytochemicals which have various roles in plant metabolism such as pollination, pigmentation and growth as well as the defense against environmental stresses, predators and microorganisms (Hurtado-Fernandez et al., 2010; Duthie et al., 2003; Heleno et al., 2015). The phenolics also display many beneficial properties for human well-being by showing antimicrobial, anti-oxidant, anti-carcinogenic, cardio-protective and anti-inflammatory properties (Karaosmanoglu et al., 2010; Andjelkovic et al., 2006; Daglia, 2012; Gutiérrez-Larraínzar et al., 2012; Diaz-Gomez et al., 2013; Cueva et al., 2010). In addition, it was presented that phenolics enhance the composition and function of gut microbiota by supporting the beneficial bacteria (Cardona et al. 2013). Since they are found in nearly all plants, the foods in human diet which were derived from plants such as fruits, vegetables, olive oil, wine, tea, etc., widely contain phenolic compounds (Lima et al., 2019). For instance, the average phenolic acid consumption by humans is presented as about 200 mg/day depending on the preferences in their diet (Heleno et al., 2015). For the absorption of the consumed phenolics, they are conjugated via methylation, sulfation and glucuronidation first in the small intestine and then in the liver. These are the main processes for their detoxification and elevation of their hydrophilicity for elimination by urination in the human body (Heleno et al., 2015). Hence, the humans benefit from the

advantageous properties every time they consume plant-derived foods when avoiding the possible toxic effects.

The plants use phenylalanine or tyrosine as precursors to naturally synthesize the phenolic compounds via shikimate pathway (Heleno et al., 2015). The characteristic structures of phenolic compounds possess one or more benzene ring and hydroxyl groups as well as other radical groups (Hurtado-Fernandez et al., 2010). The phenolic compounds can be divided into two main groups based on their skeleton nature: Polyphenols and phenolic acids. The polyphenols which contain flavonoids and tannins have more than one benzene rings in their structures. On the other hand, the phenolic acids, which are the main topic of this study, are included in simple phenolics since they have one phenol ring in their structures. (Hurtado-Fernandez et al., 2010). The phenolic acids fall into two groups due to the attachment type of carboxylic group to the benzene ring: Hydroxybenzoic acids contain the carboxylic group as directly attached while hydroxycinnamic acids possess an ethylene group for the attachment of the carboxylic group (Andjelkovic et al., 2006). The chemical structures of hydroxybenzoic acids are presented as C<sub>6</sub>-C<sub>1</sub> whereas those of hydroxycinnamic acids as C<sub>6</sub>-C<sub>3</sub> (Tripoli et al., 2005). The two phenolic acids which were investigated in this study belong to these two distinct groups. The 3-hydroxyphenylacetic acid (3-HPAA) is included in hydroxycinnamic acids group while the 4-hydroxybenzoic acid (4-HBA) is in hydroxybenzoic acids group. The molecular weight of 3-HPAA and 4-HBA are 152.15 g/mole and 138.12 g/mole, respectively (Sigma-Aldrich). They are both water-soluble simple phenolic acids with one hydroxyl group on the benzene ring. The 3-HPAA is mostly detected in olive oil wastewater (OOWW) involving high degree of polyphenols which is the by-product of olive oil extraction process (Roig et al., 2006; Zafra et al., 2006). In the study performed in IYTE, 4-HBA is detected in extra virgin olive oils in west part of Turkey (Ocakoglu et al., 2009). Although both phenolic acids only have one hydroxyl group, its position differs (Figure 1.1) (Tang et al., 2016; Fletcher et al., 2019). As a matter of fact, the number and the position of the hydroxyl groups on the benzene rings are accepted to affect the antimicrobial and anti-oxidant properties of the phenolic compounds (Lima et al., 2019; Heleno et al., 2015). The selection of the phenolic acids in this study were done not only due to having similar structures in two distinct groups but also due to having one hydroxyl group at different positions. Hence, the comparison between these phenolic acids can be more relevant in terms of their

effects on bacterial growth and the protein profile. The chemical structures of 3-HPAA and 4-HBA are presented in Figure 1.1.a and Figure 1.1.b, respectively.

The antimicrobial properties of the phenolic compounds and phenolic-containing plant extracts against pathogenic bacteria were presented in various studies. These studies indicated that phenolic compounds may be potential effective antimicrobial agents. In the study of Cueva et al., the antimicrobial effects of 13 different phenolic compounds involving 3-hydroxybenzoic acid (3-HBA), 4-HBA, 3-HPAA and 4-hydroxyphenylacetic acid (4-HPAA) were individually tested in the concentration range of 62.5-10000 µg/ ml on the different strains of pathogenic bacteria; *E. coli*, *S. aureus*, *P. aeruginosa* (Cueva et al., 2010). It was found that *E. coli* and *S. aureus* were affected by phenolic compounds with respect to their structures and in a strain-specific, dose-dependent manner. The benzoic and phenylacetic acids were presented as in the most effective phenolic compounds among the tested chemicals. However, even 1000 µg/ ml concentrations of the compounds could not inhibit the *P. aeruginosa* which indicated that higher concentrations of phenolic acids are required for these bacteria. It was concluded that the usage of the phenolic acids at physiological concentrations results in the bacterial growth inhibition depending on the bacterial strain, phenolic acid dose and structure (Cueva et al., 2010). The antimicrobial tests of phenolic compounds, gallic acid and catechin, were performed on *Helicobacter pylori* which are the Gram negative bacteria causing peptic ulcer (Diaz-Gomez et al., 2013). Regardless of being applied individually or in combination, these phenolic compounds resulted in reduced bacterial growth in a dose-dependent manner. In addition, gallic acid resulted in higher antimicrobial effect than catechin. Thus, the antimicrobial effect was found as phenolic compound type-dependent.

In another study, Sanhueza et al. tested the antimicrobial effects of phenolic acids and flavonoids including gallic acid, vanillic acid, syringic acid and catechin as well as various antibiotics on clinical strains of *S. aureus* and *E. coli* (Sanhueza et al., 2017). In addition, they compared those with the effect of grape pomace extract which contains all of the tested phenolics according to their HPLC study as well as testing the synergistic effects of the extract with antibiotics. The results showed that the tested bacteria were resistant to the antibiotics while phenolic compounds displayed high antimicrobial effects except (+)-catechin. The MIC values for phenolic acids were in the range of 0.062-3 mg/ml and the MIC values of flavonoids were found in 0.1-1.5 mg/ml

range for *S. aureus*. Whereas the phenolic acids showed MIC values in the range of 0.2-2.5 mg/ml and flavonoids showed 0.2-5 mg/ml for *E. coli*. They concluded that MIC values of the phenolic acids and flavonoids were similar to the MIC values of grape pomace extracts against antibiotic resistant bacteria (Sanhueza et al., 2017). Hence, the antimicrobial effect of the grape pomace extract may be due to its phenolic compound ingredients. Additionally, when the antibiotics were applied as a mixture with grape pomace extract, a synergistic effect was detected which may show that phenolic acids aid the bacterial growth inhibition of antibiotics (Sanhueza et al., 2017). Likewise, the study of Shen et al. indicated that the blueberry extract and the phenolic compounds chlorogenic acid, ellagic acid, quercetin and quercetin-3-galactoside, which were found in high levels in the blueberry extract, exhibited a dose-dependent bacterial growth inhibition of food-borne pathogens *L. monocytogenes* and *Salmonella* Enteritidis (Shen et al., 2014). Among the phenolic compounds tested, the least effective phenolic compound was found as the chlorogenic acid (500 µg/ml) while the most effective one was the ellagic acid (44 µg/ml) against *L. monocytogenes* and *Salmonella* Enteritidis (Shen et al., 2014). It was concluded that the phenolic contents of blueberry extracts may be the reason of the antimicrobial effect (Shen et al., 2014).

The distinct antimicrobial effects of the phenolic compounds are demonstrated on nosocomial or food-borne pathogenic bacteria in many studies. These studies mostly point out the higher antimicrobial effect of phenolic acids is associated with their smaller structures among all the phenolic compounds. It can be speculated that the small sizes of phenolic acids may lead the strong interactions with membranes or other targets in bacteria (Lima et al., 2019). For instance, outer membrane of Gram negative bacteria may be easily crossed by phenolic acids due to their small structures while the membrane does not usually allow big and hydrophobic molecules to be transported (Cueva et al., 2010). Relatedly, the antimicrobial effects of the phenolic compounds must be occurred due to the targeting some structures or metabolic pathways of the bacteria. Unfortunately, it is known that the antimicrobial agents can target human proteins as well as bacterial proteins which reduce the success of antimicrobial therapy (Chavali et al., 2012). Hence, the determination of the pathogen protein targets may be a starting point for the elucidation of action mechanisms of these compounds not only for further studies of future antimicrobial therapies but also elimination of the compounds targeting human proteins, leading specific antimicrobial agents for pathogens. A general

idea for possible pathogen protein targets of the antimicrobial agents can be achieved by using the proteomic approaches since the obstruct of checkpoints of important metabolic pathways is accepted as a useful way for antimicrobial therapy (Garg et al., 2018).

#### **1.4. Proteomic Investigation of Antimicrobial Effects**

The -omics sciences, including genomics, proteomics, transcriptomics, metabolomics, glycomics or the combinations of those, are accepted as dependable approaches with their related bioinformatics analyses due to their allowance to obtain wide informations that give clues about the action mechanisms of the bioactive compounds (Maldonado-Carmona et al., 2019). Among those, the proteomics may display useful results since the protein profiles possess the final state of the cell after the modifications. Hence, using the proteomics is a dependable approach for the determination of the bacterial protein profile changes for adaptations to different conditions such as growing in the presence of a chemical compound and it can aid reliable results in potential target determinations in the antimicrobial discovery area (François et al., 2010; Navare et al., 2015). For instance, the changes in the proteins functioned in bacterial cell processes which are required for the growth and survival can indicate the favorable targets (Lee et al., 2015). For this purpose, besides gel-based proteomic techniques, the mass spectrometry coupled with the liquid chromatography (LC) as well as electrospray ionization (ESI) is also a popular technique namely “Liquid Chromatography Electrospray Ionization Tandem Mass Spectrometry” (LC-ESI-MS/MS) (shot gun proteomics) with higher sensitivity and speed (François et al., 2010, Walther and Mann, 2010). In this technique, the protein samples are digested as the first step either with in-gel or in-solution digestion depending on the preference of a gel-based first separation of proteins or not, respectively (Choksawangkarn et al., 2012). The fractionation which is performed after digestion step provides the enhancement of analytical dynamic range and proteome coverage (Yang et al., 2012). After that, the identification of high numbers of peptides can be obtained since this technique possesses two consecutive separation steps for peptides: LC and ESI-MS/MS (Stapels et al., 2004; Walther and Mann, 2010). The first separation of the peptides is carried out by High Pressure Liquid Chromatography (HPLC) by either strong cation exchange (SCX)

chromatography depending on the charges or pH reversed-phase (RP) chromatography depending on the hydrophobic interactions (Batth et al., 2014). Either low or high pH HPLC columns can be used in RP chromatography (Wang et al., 2011). Since it results in enhanced protein identification, more clean samples excluding desalting, reducing sample loss as well as process time, high pH RP is more useful than low pH RP or SCX (Yang et al., 2012). Prior to second separation by HPLC using low pH columns, the samples are charged and transferred to gas form by ESI which allow the detection of the molecules in an electric field (Walther and Mann, 2010). After the data is obtained and processed for the protein identification by search engines such as MASCOT (Walther and Mann, 2010), the functions of the proteins are determined in online databases (i.e. Uniprot, KEGG, Swissprot). The interaction network of the proteins can be detected for a deeper insight of the changes in the bacterial cell systems by databases such as STRING (Search Tool for the Retrieval of Interacting Genes/Proteins) which is a widely-used, open source database (<http://string-db.org/>) (Cafarelli et al., 2017). The interaction network of genes/proteins stands for the representation of the interactions between the genes/proteins of interest as a graphic by displaying each gene/protein as a node and their interaction as the connecting edge. The interaction informations are obtained from various sources such as primary databases as well as the predicted interactions via statistical methods and the interactions can be physical (direct) or functional (indirect) which are indicated by colors (Miryala et al., 2018; Cafarelli et al., 2017).

After the proteome elucidation, the protein data can be validated at the transcriptomic level by the technique named real time quantitative PCR (RT-qPCR). In this technique, the relative fold change of the gene expression of the protein of interest is determined based on the normalization to the expression of the reference gene and control group. A reference gene must be simultaneously analyzed with the investigated genes and specific primers for each gene must be designed by online tools such as Primer BLAST. The reference gene of the bacteria can be determined among the housekeeping genes such as *gyrB*, *rpoA*, *rpoB*, *oriC*, *dnaJ*, and *rplI* as well as 16S rRNA genes depending on the properties of the bacteria and the experimental conditions (Takahashi et al., 2017). For instance, in the study of Llanes et al. it was shown by RT-qPCR and immunoblotting that the overexpression of the genes of MexAB-OprM and MexXY efflux pumps were simultaneous (Llanes et al., 2004). In that study, 12

multidrug resistant *P. aeruginosa* strains were investigated and *rpsL* gene was used as the housekeeping gene for RT-qPCR. Based on the results, they concluded that the simultaneous overexpression of the efflux pump genes might aid the enhancement of the resistance of clinical strains (Llanes et al., 2004). Similarly, Dumas et al. used this technique for the investigation of expression of antibiotic resistance genes in wild-type and mutant, clinical and laboratory strains of *P. aeruginosa* (Dumas et al., 2006). Since the Mex drug efflux pumps, AmpC  $\beta$ -lactamase and OprD which is the porin of carbapenem are related to the antibiotic resistance of *P. aeruginosa*, they elucidated the expression of the genes of these proteins by RT-qPCR. As the reference gene, they also used ribosomal *rpsL* gene to normalize the results. Their results presented a high fold-increase in the expression of aforementioned genes and they concluded that RT-qPCR is a reliable technique for the investigation of expression of antibiotic resistance genes (Dumas et al., 2006). It is clear that *rpsL* gene, which is a 16S ribosomal protein gene, was used as the housekeeping gene in the RT-qPCR studies in the literature. Thus, this gene was chosen as the reference gene in our protein data validation study which was performed via RT-qPCR. Although the data of proteome and transcriptome may not always be overlapped due to the modifications of the proteins during or after their maturation, this type of validation is still accepted as a reliable technique to confirm the expression change of gene of protein of interest. For instance, Ma et al. investigated the mechanism of action of daptomycin antibiotic on *S. aureus* at the proteomic level by determining the whole proteome via LC-MS/MS and then validated the results via RT-qPCR for the genes of diphosphate kinase (NDK) and 5'-nucleotidase (NT5) enzymes by normalizing the results based on housekeeping gene, triosephosphate isomerase (TPI) gene (Ma et al., 2017). The proteomic data showed that the profile of membrane proteins and DNA metabolism were affected in the presence of daptomycin. The results displayed the relevant gene expression changes with the protein data by the increased expression of NDK gene and decreased expression of NT5 gene. These are both important enzymes which function in the purine metabolism. Thus, the changes of these proteins were not only confirmed at the proteomic level but also confirmed at the transcriptomic level. They concluded that doptamycin displayed a dual action mechanism by damaging the cell membrane and DNA metabolism of *S. aureus* which may explain its mode of action as a bacteriocidal antibiotic (Ma et al., 2017). In addition, various studies exist in the literature for the determination of the changes in

the protein profiles of bacteria, enlightening the bacterial metabolisms as well as the answers to different conditions which can aid the development of antimicrobial agents. In the study of Carrera et al., the proteome of 20 food-borne strains of *Staphylococcus aureus* were investigated by in-solution proteolytic digestion and LC-ESI-MS/MS analysis (Carrera et al., 2017). They used UniProt database to analyze the data sets and they determined the networks of the proteins by gene ontology (GO) analysis. They discussed that most common identified proteins of these strains were surface-associated proteins that were related to pathways and networks of energy, lipid metabolism and virulence (Carrera et al., 2017) which may be a clue for the target of new antimicrobials against these bacteria. Kılıç et al. elucidated the *P. aeruginosa* protein profile against chromium (VI) toxicity via proteomic approach. Since these bacteria are resistant against chromium (VI), the identifying the overexpressed proteins of these bacteria in high levels of the chromium (VI) may show the resistance scope of the bacteria (Kılıç et al., 2010). Since they used a gel based method, a small quantity of the proteins were detected. They used in-gel digestion of the protein spots prior to LC-ESI-MS/MS and determined 21 proteins which were expressed differently than the control group. The upregulated cytosolic proteins were detected which are related to stress response, protein biosynthesis, energy production metabolism and response to oxidative stress. The membrane bound proteins were upregulated functioned in the stress response, some ribosomal structural proteins, outer membrane proteins and energy metabolism proteins. Thus, the proteomic approach was successfully used to aid enlightening the resistance mechanism of *P. aeruginosa* against chromium (VI). The study of Sharma et al. demonstrated the proteome of clinical strain of *Klebsiella pneumoniae* in the presence of meropenem (a type of carbapenem) (Sharma et al., 2019). Since these bacteria possess a carbapenem resistance, Sharma et al. aimed to bring out the resistance mechanism of the bacteria to be able to detect the molecular targets to combat the resistant strains. They used LC- MS/MS and related bioinformatics tools, Gene Ontology, KEGG and STRING and demonstrated that 52 proteins were over expressed which might be used for bacterial resistance and survival. The overexpressed proteins were related mainly to protein translational machinery complex, DNA/RNA modification, carbapenems cleavage, energy metabolism and intermediary metabolism (Sharma et al., 2019). Thus, whole proteome of *Klebsiella pneumoniae* was enlightened in terms of carbapenem resistance-related proteins for further studies of antimicrobial

developments. Li et al. used the combination of proteomics and metabolomics data for the determination of the *E.coli* answer to ciprofloxacin (Li et al., 2018). They performed LC-MS/MS for protein identification of the bacteria growth in the environments with or without ciprofloxacin and compared those. They presented the changed protein profile with 143 decreased and 147 increased expressions. When they integrated proteomic data with the metabolomic data, they suggested a possible mode of action of this drug as blocking the DNA replication while increasing the DNA gyrase and DNA topoisomerase I. In addition, the ciprofloxacin exposure resulted in the changes of tRNA biosynthesis with the enhancement of aminoacyl-tRNAs ligases, but diminished the biosynthesis of related amino acids (Li et al., 2018).

As a consequence, proteomic approach is used for comparison between chemical of interest-treated or non-treated groups of the same organism to determine the molecular effects of the chemical on the organism. To the best of our knowledge, although the antimicrobial effects of the phenolic compounds are presented in a plenty of studies in the literature, the studies focusing on the molecular mechanism of their antimicrobial effects are very limited. Since our study aims to determine the changes in the whole protein profile of *P. aeruginosa* in the presence of phenolic acids, it may aid to fulfill the lack of information about the antimicrobial effects of these compounds at the molecular level. These informations can be a starting point to guide more detailed studies about the phenolic acid mode of action, in the future.

## **1.5. Encapsulation of Phenolic Acids**

Nowadays, the encapsulation of the bioactive compounds, such as phenolic compounds, is a popular concept in the studies related to biomedical field. Although the phenolic acids are promising candidates for alternative treatments against pathogenic bacteria showing distinct antimicrobial effects, they have broad ranges of aqueous solubilities and rapid degradation profiles which may decrease their antimicrobial potential. The encapsulation of the phenolic acids into nanoparticles can solve these problems (Krausz et al, 2015). Nanoparticles are the particles which have a size range between 1-100 nm (Capaldi Arruda et al., 2015). But the ones that have sizes below 1000 nm are also accepted as nanoparticles in pharmaceutical science (Li et al., 2015). They are useful for encapsulation of drugs to be able to increase their stability and to

control their release properties. For encapsulation of the phytochemicals such as phenolic compounds into nanoparticles, hydrogen bonds and hydrophobic interactions are effective. These interactions encapsulate the phenolics in the nanoparticles not only to facilitate the aqueous solubility of phenolics but also to decrease the oxidation and/or degradation of the phenolics (Li et al., 2015). In the treatment of infections, the usage of the nanoparticles can be an alternative therapy route (Andonova and Urumova, 2013). Encapsulation would provide phenolic acids an increased stability, controlled release and protection against environmental changes. Relatedly, the antimicrobial effects of the phenolics can be achieved in higher levels when they are encapsulated compared to their effects of free form. In addition, because the resistance is not occurring in bacteria against phenolic acids so far, they can be alternative agents in infection treatments. In the encapsulation processes, polymers like chitosan and alginate are widely used. Chitosan is a biodegradable, biocompatible, non-toxic material with antimicrobial activity which can be used for variable applications. It is produced from chitin via deacetylation of chitin under alkaline conditions or by chitin deacetylase enzyme (Jayakumar et al., 2010). It has ability to comprise with vitamins, minerals, oils, proteins and biologically active natural products to form functional substances (Tang et al., 2013; Azevedo et al., 2014; Budnyak et al., 2016; Deka et al., 2016; Wu et al., 2018; Moschona and Liakopoulou-Kyriakides, 2018). Because of its extensive usage, easy preparation, known antimicrobial property and biodegradable nature, chitosan can be a good choice for encapsulation of phenolic acids for using as a possible treatment of infections in the future. Alginate is another important material which is used in encapsulation processes. It is an anionic polymer that is obtained from algae which consists of glucuronic acid and mannuronic acid residues. It is a commonly used material for encapsulation of chemicals because of its easy-to-use, non-toxic, biodegradable and biocompatible nature (Paques et al., 2014) and ability to synthesize hydrogels in the presence of divalent cations (Yang et al., 2011).

The alginate-chitosan nanoparticles, which possess alginate as a pre-gel and chitosan as a covering material, can be obtained depending on the electrostatic interactions of carboxyl groups of alginate and amino groups of chitosan (Zimet et al., 2018). In the production of alginate-chitosan nanoparticles, ion-gelation technique is a widely-used technique in which calcium chloride is used as a cross linker to make the pre-gel of the alginate. The usage of calcium in this process result in the linkage of the

alginate monomers to each other making an egg-box-shaped structure in which the drug of interest can be captured (Wu et al., 2018; Zimet et al., 2018). Then, the coating of alginate which is an anionic polymer with chitosan which is cationic, results in alginate-chitosan nanoparticles. This type of coating presents a better coating because of the obtained polyelectrolyte complex with an increased stability (Paques et al., 2014). Since the phenolic acids that were used in this study are water soluble, alginate-chitosan nanoparticles were expected to provide a durable coat for better protection for these phenolic acids.

The important parameters of successful nanoparticle production are the homogeneity, physicochemical properties, size and shapes of the particles and the behavior. After the nanoparticle production, these properties can be characterized via some analyses (Bhattacharjee et al., 2016) such as dynamic light scattering (DLS), Fourier transform infrared spectrometry (FTIR) and scanning electron microscopy (SEM). Dynamic light scattering is a technique that measures the average hydrodynamic diameters of the particles (particle size) in a solution (Krausz et al., 2015; Bhattacharjee et al., 2016) and shows the uniformity of the tested sample. If the DLS result of a solution demonstrates a single peak, it can be concluded that the particles in that solution have a uniform nature (Mohammadi et al., 2016) while more than one peak of the same sample demonstrates the particles may not be homogeneous. In addition, the polydispersity index (PDI) values of the samples which are obtained from DLS data also give opinion about the homogeneity of the particles. The PDI value smaller than 1, displays that the particles in the solution show a narrow size distribution which leads to homogeneity in size (Liu et al., 2018; Qi et al., 2004). The FTIR measurements of the nanoparticle samples is useful to demonstrate that the produced nanoparticles display a unique spectrum as a unique compound. The spectra of the polymers and phenolic acids either individually and nanoparticle forms can be detected and compared for presenting the production of nanoparticles resulted in the eventual unique bonds (Mladenovska et al., 2007). Additionally, the exact shapes and diameters of the particles can be visualized under electron microscopy since DLS show only the average and hydrodynamic diameters.

The studies that focus on the antimicrobial agents loaded in chitosan nanoparticles or alginate-chitosan nanoparticles are increasing in the literature which present efficient results for the nanoparticles as antimicrobial agents. Liu et al. tested the

antimicrobial properties of  $\epsilon$ -polylysine loaded alginate-chitosan nanoparticles on *E. coli*, *B. subtilis*, *S. aureus* and *M. luteus* (Liu et al., 2018) by agar diffusion and the results showed that  $\epsilon$ -polylysine loaded alginate-chitosan nanoparticle showed high antimicrobial effects by producing distinct inhibition zones (Liu et al., 2018). In addition, the encapsulation of  $\epsilon$ -polylysine displayed three-fold increase in antimicrobial activities than its free form on the same bacteria (Liu et al., 2018). In the study of Jamil et al., the chitosan nanoparticles loaded with kefzole, an antibiotic, and tested on multidrug resistant *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* by agar diffusion (Jamil et al., 2016 (a)). It was demonstrated that the antibiotic alone did not produced zones of inhibition while encapsulated antibiotics showed antimicrobial effects in an increasing manner depending on the increasing concentrations of the antibiotics in the nanoparticles. This may demonstrate that the encapsulation of the drugs can enhance their antimicrobial properties (Jamil et al., 2016 (a)). In addition to agar diffusion studies, the bacterial growth studies also demonstrate the increased effects of the agents after encapsulation. Jamil et al. investigated the growth of MRSA and *E. coli* in the presence of cardamom essential oil and cardamom essential oil loaded chitosan nanoparticles individually (Jamil et al., 2016 (b)). The results demonstrated that cardamom essential oil caused no inhibition on the growth of both bacteria while both null nanoparticles and loaded nanoparticles resulted in growth control for the first 48 hours. After 48 hours, the complete inhibition was continued for only cardamom oil loaded chitosan nanoparticles until seven days. (Jamil et al., 2016 (b)). In another study, rosmarinic acid, protocatechuic acid and 2,5-dihydroxybenzoic acid were encapsulated into chitosan nanoparticles by using low and high molecular weights, individually and tested on the growth of various pathogens; *Bacillus cereus*, *Escherichia coli* O157, *Listeria innocua*, *Staphylococcus aureus*, *Salmonella typhimurium* and *Yersinia enterocolitica* (Madureira et al., 2015). These nanoparticles displayed high antimicrobial effects on the tested bacteria with higher than 70% inhibition of the growth with different inhibition percentages for each organism. Rosmarinic acid loaded nanoparticles presented the highest effect with more than 90% inhibition while protocatechuic acid loaded nanoparticles presented the lowest percent inhibition (Madureira et al., 2015). Thus, the phenolic compound loaded nanoparticles may show a strain-specific antimicrobial effect due to the type of loaded phenolic compound. Based on these knowledge, it was aimed to elucidate the effects of phenolic acids, 3-

HPPA and 4-HBA, on the growth of widely distributed, serious pathogenic bacteria, *P. aeruginosa*. Additionally, it was aimed to determine their effects on the whole proteome of the bacteria in order to show their antimicrobial effects at the molecular level. On the other hand, the investigations on the encapsulation of these phenolic acids in terms of production, characterization and antimicrobial effects on various pathogenic bacteria were also aimed. The main courses of the study are:

1. The determination of the growth behavior and morphological state of *P. aeruginosa* in the presence of water-soluble phenolic acids *in vitro*.
2. The determination of the changes in the total protein profile of *P. aeruginosa* in the presence of phenolic acids via LC-ESI-MS/MS and validation of the protein data at the transcriptomic level via real time quantitative PCR.
3. The production and demonstration of the potential usage route of alginate-chitosan nanoparticles loaded with water-soluble phenolic acids *in vitro*.

## CHAPTER 2

# EFFECTS OF THE PHENOLIC ACIDS ON GROWTH AND MORPHOLOGY OF *Pseudomonas aeruginosa*

### 2.1. Introduction

*Pseudomonas aeruginosa*, which can be isolated from various environments, is a health-threatening opportunistic pathogen. It causes various infections in humans worldwide. For instance, in nosocomial infections, *P. aeruginosa* is accepted as one of the most important pathogenic bacterium (Breidenstein et al., 2011). Although it is a rare resident of human microbiota, it may be found up to 50% of the microbial flora of the patients during the hospitalization period. It is difficult to cure the infections caused by these bacteria on the fact that they require an extensive antibiotic therapy. However, *P. aeruginosa* has resistance to many antimicrobials such as penicillins, cephalosporins, carbapenems, monobactams (Poole, 2011) and fluoroquinolones (Lister et al., 2009). Even if antibiotic resistance is not observed in some strains, they can gain resistance during the treatment (Potron et al., 2015). Besides their multidrug resistance (Strateva and Yordanov, 2009), the biofilm-formation property of these bacteria (Andonova and Urumova, 2013) make it difficult to combat. These properties make the infections of *P. aeruginosa* life-threatening with high mortality and morbidity rate (Aloush et al., 2006; Gill et al., 2018). Therefore, new antimicrobial agents are in search.

Phenolic compounds are naturally synthesized chemicals by almost all plants as secondary metabolites. (Hurtado-Fernandez et al., 2010). They have roles in plants for plant metabolisms in addition to protection against bacteria (Duthie et al., 2003). They have various beneficial properties for humans such as antimicrobial, anti-oxidant, anti-carcinogenic, cardio-protective and anti-inflammatory properties (Karaosmanoglu et al., 2010; Andjelkovic et al., 2006; Daglia, 2012; Gutiérrez-Larraínzar et al., 2012; Diaz-Gomez et al., 2013; Cueva et al., 2010). The common structure of simple phenolic compounds consist of a benzene ring with one or more hydroxyl groups and different functional groups (Hurtado-Fernandez et al., 2010). Hydroxybenzoic acids and

hydroxycinnamic acids are two main groups of phenolic acids. In hydroxycinnamic acids, carboxylic group is attached to benzene ring via an ethylene group. However, in hydroxybenzoic acids, carboxyl group is directly attached to the benzene ring (Andjelkovic et al., 2006). The phenolic acids that will be used in this study are 3-Hydroxyphenylacetic acid (3-HPAA) and 4-Hydroxybenzoic acid (4-HBA) which belong to hydroxycinnamic acids and hydroxybenzoic acids, respectively. They are simple phenolic acids with one phenol ring and they are water soluble.

The objectives of this study were to determine the minimum inhibitory concentrations (MIC) and minimum bacteriocidal concentrations (MBC) of 3-HPAA and 4-HBA on *P. aeruginosa* and to investigate morphological changes of the bacteria in the presence of subinhibitory concentrations of these phenolic acids.

## **2.2. Materials and Methods**

The effects of phenolic acids on *P. aeruginosa* were investigated by spectrophotometric and enumeration methods prior to scanning electron microscopy.

### **2.2.1. Bacterial Strain and Culture Conditions**

*Pseudomonas aeruginosa* (ATCC 27853) was grown in Mueller Hinton broth (MHB) and Mueller Hinton agar (MHA) media (Fluka) at 37°C without shaking. Bacterial growth behavior was determined by plotting the growth curve of the bacteria during 24 hours (Appendix A). The bacteria were maintained on MHA at 4°C which were refreshed every week or long term-stock cultures when necessary. The long term-stock cultures of the bacteria were kept at -80°C in MHB containing 20% glycerol.

### **2.2.2. Antimicrobial Activities of Phenolic Acids**

A single colony of *P. aeruginosa* was inoculated into 4 ml of MHB media and the bacteria were incubated at 37°C for 18 hours (overnight). Spectrophotometric measurement was performed to determine the optical density (O.D.) of overnight bacterial culture at 600 nm. The phenolic acids (3-HPAA and 4-HBA) were obtained

commercially (Sigma-Aldrich). The solutions of 3-HPAA and 4-HBA were prepared freshly in the required concentrations in sterile double-distilled water (ddH<sub>2</sub>O) and added to MHB at the time of each experiment. The final bacterial load of 10<sup>6</sup> cfu/ml from overnight culture was inoculated into phenolic acids containing MHB. Blanks of test group were the phenolic acid solution prepared in required concentration and MHB without addition of bacteria. Control group also had 10<sup>6</sup> cfu/ml final bacterial load from overnight culture into MHB without phenolic acid addition. Blank of control group was MHB. The O.D. of the treated and untreated cultures were measured at 600 nm at 0th and 24th time points of the growth. At the same time, the cell viabilities of the cultures grown for 24h were tested by enumeration method on MHA. The initial bacterial load was also confirmed by enumeration method in each experiment, throughout the study.

### **2.2.3. Determination of *P. aeruginosa* Morphology**

The morphological properties of *P. aeruginosa* treated with/without phenolic acids were determined by scanning electron microscopy (SEM) and the colour changes of the bacterial cultures were clearly detected by naked eye. The bacterial cultures were prepared with the same protocol of antimicrobial studies (see Section 2.2.2). After 24 h of growth, the cells of each group was harvested by centrifugation at 14.000 x g for 2 minutes. The pellets were washed with 0.1% peptone twice and resuspended in 0.1% peptone. After placing 10 µl of these samples on aluminium (Al) foil, they were dried for 15 minutes at 37°C. The prepared samples were placed on the carbon band containing, metal grids and covered with gold for 2 minutes. Then, these samples were examined under scanning electron microscope (Phillips XL-30S FEG) at İYTE-MAM.

To observe the color changes in the broth cultures, the samples were prepared as explained in section 2.2.2. After 24 h of incubation, the cultures were photographed to demonstrate the colour differences between the control group and phenolic acid treated groups.

## **2.3. Results and Discussion**

The investigated, water soluble phenolic acids (3-HPAA and 4-HBA) demonstrated strong antimicrobial activity against *P. aeruginosa*. The MIC and MBC

values were determined for both phenolic acids as well as their effects on the bacterial morphology and culture color.

### **2.3.1. Antimicrobial Effects of Phenolic Acids on *P. aeruginosa***

The antimicrobial effects of 3-HPAA and 4-HBA were determined on *P. aeruginosa* both spectrophotometric and viable cell count studies. The range of tested concentrations of 3-HPAA and 4-HBA were 1.7-2.3 mg/ml and 1.5-2.1 mg/ml, respectively. The growth curves of *P. aeruginosa* in the presence of 3-HPAA and 4-HBA with the indicated concentrations were presented in Figure 2.1a and b. The MIC values were determined as 2.1 mg/ml for 3-HPAA and 1.9 mg/ml for 4-HBA (Figure 2.1a and b). Since no survivors were detected in the presence of 2.3 mg/ml 3-HPAA and 2.1 mg/ml 4-HBA (Table 2.1), these concentrations were considered as MBC of the tested phenolic acids. The difference in concentration values for MIC and MBC arose from the dose-dependent nature of antimicrobial effects of phenolic acids. Both phenolic acids demonstrated similar antimicrobial patterns. However, it could be concluded that 4-HBA has higher antimicrobial effect on *P. aeruginosa* than that of 3-HPAA, since the lower concentrations of 4-HBA showed the higher antimicrobial effect. For instance, 1.7 mg/ml 3-HPAA caused 31% inhibition while the same concentration of 4-HBA caused 71% inhibition (Table 2.1). This might be due to the structural differences between 3-HPAA and 4-HBA: Since, their carboxyl groups are attached to the benzene ring differently, they belong to different phenolic acid groups. While the carboxyl group of 3-HPAA (a member of hydroxycinnamic acid) is attached to benzene ring via an ethylene group, it is directly attached to the benzene ring in 4-HBA (a member of hydroxybenzoic acid) (Andjelkovic et al., 2006). Although they both contain one hydroxyl group attached, their positions on the benzene ring are different. These structural differences might be the reason for the slight variations of the antimicrobial effects of 3-HPAA and 4-HBA.

### **2.3.2. The Morphology of *P. aeruginosa***

The colour differences between bacterial cultures that were treated and untreated with 3-HPAA and 4-HBA were presented in Figure 2.2 a and b, respectively. The

culture of *P. aeruginosa* has a distinct greenish-blue colour as a result of the mixture of blue color from the bacteria and yellow color from the media (Rada and Leto, 2013). The pigment called pyocyanin produced by *P. aeruginosa* is the reason for the blue color (Rada and Leto, 2013). When the *P. aeruginosa* cultures were grown in the presence of 3-HPAA or 4-HBA, the blue color was not observed (Figure 2.2). The significantly distinct greenish blue color was observed in the control groups, after 24 hours of incubation without phenolic acids.

Our results were consistent with the study of Ugurlu et al. which presented that the the solutions of vanillic acid, caffeic acid, cinnamic acid and ferulic acid (phenolic acids) treatment reduced the pyocyanin production in *P. aeruginosa* (Ugurlu et al., 2016).

The morphological properties of untreated (Figure 2.3 a and b), 3-HPAA treated (Figure 2.3 c and d) and 4-HBA treated (Figure 2.3 e and f ) *P. aeruginosa* were investigated by SEM analysis. It was clearly shown that the surface of the bacteria have a collapse line especially in 3-HPAA treatment. The collapse on the bacterial surfaces demonstrate that the phenolic acids might affect the envelope structure (characteristic structure of Gram negative bacteria made up of two membranes with a thin peptidoglycan layer in between) (Stinnett et al., 1973) of *P. aeruginosa*.

Table 2.1. Percent inhibitions and cell viabilities of phenolic acids for *P. aeruginosa*.

3-HPAA			4-HBA

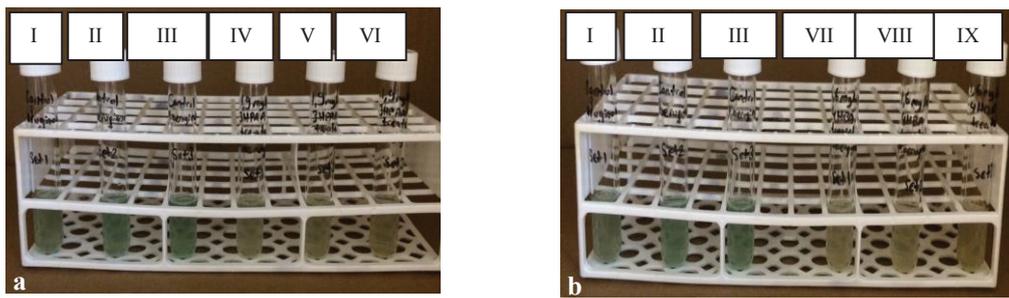

Figure 2.2. The comparison of colors of *P. aeruginosa* cultures after 24 hours of incubation. Control (a and b-I, II, III, 3 sets); 1.9 mg/ml 3-HPAA treated (a-IV, V, VI, 3 sets) 1.6 mg/ml 4-HBA treated (b-VII, VIII, IX, 3 sets) cultures.

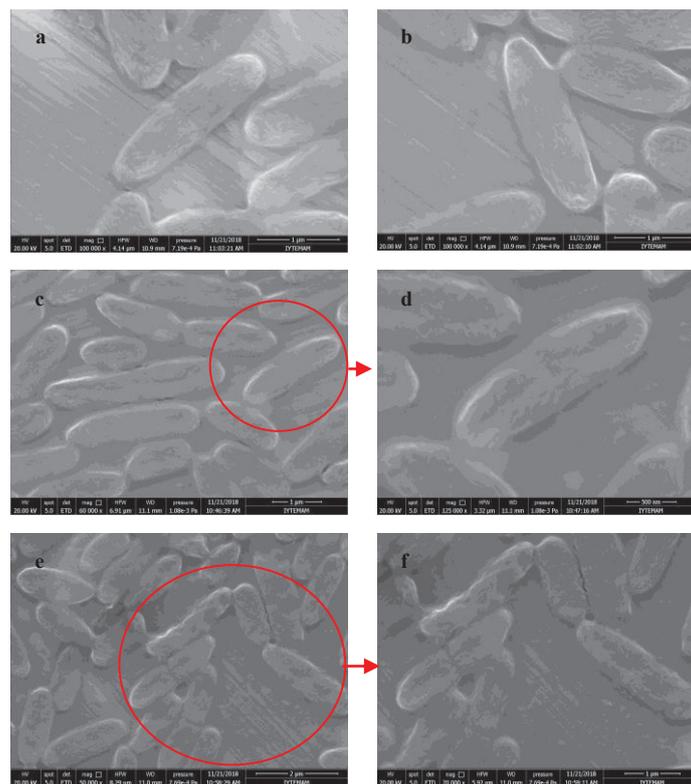

Figure 2.3. The morphology of *P. aeruginosa*. Control cells at 100,000x magnification (a,b); 3-HPAA treated cells at 60,000x magnification (c) and at 125,000x magnification (d); 4-HBA treated cells at 50,000x magnification (e) and at 70,000x magnification (f) at the 24th h of growth.

## CHAPTER 3

# MOLECULAR INVESTIGATION OF ANTIMICROBIAL EFFECTS OF THE PHENOLIC ACIDS ON *P. aeruginosa*

### 3.1. Introduction

*Pseudomonas aeruginosa* which is one of the most important pathogenic bacterium worldwide (Faure et al., 2013) has resistance to many antimicrobials such as penicillins, cephalosporins, carbapenems, monobactams (Poole, 2011) and fluoroquinolones (Lister et al., 2009). The infections of *P. aeruginosa* have a high mortality and morbidity rate (Gill et al., 2018). It is challenging to treat the infections caused by these bacteria since an extensive antibiotic therapy is required. (Zhou et al., 2015). Therefore, new antimicrobials other than antibiotics are in search (Mathieu et al., 2016). Phenolic compounds, which are naturally synthesized by almost all plants as secondary metabolites (Hurtado-Fernandez et al., 2010), are accepted as promising antimicrobial agents. Among their many beneficial properties (as antimicrobial, anti-oxidant, anti-carcinogenic, cardio-protective and anti-inflammatory) the antimicrobial effects of phenolic acids were presented in many studies (Karaosmanoglu et al., 2010; Andjelkovic et al., 2006; Daglia, 2012). However, these studies mostly focus on the antimicrobial effects of the phenolic acids without investigating the molecular mechanisms which is required for the development of new antimicrobial treatments.

The shot-gun proteomics is a reliable technique for presenting the molecular mechanisms (Wang et al., 2014) which includes a useful two step technique called LC-ESI-MS/MS. The usage of combination of two techniques allows the identification of more peptides than usage of one technique in peptide separation (Stapels et al., 2004). Since in the LC-ESI-MS/MS technique the peptide mixture is analyzed consecutively by liquid chromatography (LC) and electrospray ionization (ESI) coupled with mass spectrometry, it result in the identification of a large quantity of peptides. This technique includes these general steps: proteolytic digest, LC-ESI, MS/MS and data analysis (Walther and Mann, 2010). Briefly, in MS based shot-gun proteomics

technique, the protein samples undergo a proteolytic digest to obtain peptide samples which will be analyzed. The proteolytic digestion of the proteins can be performed either by in-gel digestion or in-solution digestion (Choksawangkarn et al., 2012). Following the proteolytic digestion the fractionation of the protein samples can be performed since the fractionation of the protein samples before LC-MS/MS analysis increases both the analytical dynamic range and proteome coverage (Yang et al., 2012). The first separation of peptides prior to tandem mass spectrometric analysis is carried out by liquid chromatography (The first HPLC step) either by strong cation exchange (SCX) chromatography which is charge based or (low or high) pH reversed-phase (RP) which depends on the hydrophobic interactions (Wang et al., 2011; Batth et al., 2014). However, the usage of high pH RP as the first separation rather than SCX or low pH RP results in more clean samples which eliminate the desalting step and an increase in the number of proteins identified (Yang et al., 2012). Therefore, usage of high pH RP gives better results since it decreases the samples loss and the process time while increasing the protein identification (Yang et al., 2012) and resolution (Batth et al., 2014). In the second HPLC step, coupled with electrospray ionization (ESI), low pH columns are used for the samples which become charged and transformed to gas form right before the HPLC by electrospraying (ESI). The gas phase allows the mass to charge ratio of the molecules can be determined in a static or dynamic electric field (Walther and Mann, 2010). Then the obtained data are processed by MASCOT (one of the widely used search engines) for protein identification which is followed by protein function search in online databases (i.e. UniProt, KEGG, SwissProt) (Walther and Mann, 2010).

The studies that focus on the investigation of protein profile of microorganisms by mass spectrometry exist in the literature either on the comparison of proteome of different strains (Carrera et al., 2017) or the comparison of toxic compound treated and untreated groups of the same strain (Kılıç et al., 2010).

In this study, the determination of protein profile of *P. aeruginosa* treated with or without phenolic acids were performed by LC-ESI-MS/MS. The phenolic acids which were used in this study were belong to two different groups of phenolic acids: hydroxycinnamic acids (3-HPAA) and hydroxybenzoic acids (4-HBA). The aim of this study was to present the changes in the protein profile of *P. aeruginosa* in the presence of 3-HPAA or 4-HBA which showed a dose-dependent antimicrobial activity on the bacteria (Chapter 2). We hypothesized that, if growth pattern of the bacteria changes in

the presence of phenolic acids, then; some changes in the proteome of the bacteria would be expected after the treatment with subinhibitory concentrations. The investigation of the proteomic changes of the bacteria after phenolic acid application would be the first step in the determination of the molecular action mechanism of phenolic acids by which the molecular targets of antimicrobial effects would be presented.

## **3.2. Materials and Methods**

The changes in total protein profile of *P. aeruginosa* were investigated after treatments with subinhibitory concentrations of 3-HPAA (1.9 mg/ml) or 4-HBA (1.6 mg/ml) via LC-ESI-MS/MS analysis and MASCOT software by using reference database of *P. aeruginosa* in UniProt. The proteins that were undetected or newly detected after the treatment were grouped by Venn diagram analysis. The functions of the proteins were determined by UniProt and were grouped based on the biological processes according to which they were involved. The STRING database was used for the visualization of the interaction network of these group of proteins to suggest the effects of phenolic acids on *P. aeruginosa* at the proteomic level.

### **3.2.1. Bacterial Growth Conditions and Phenolic Acid Treatment**

During the experiments; *Pseudomonas aeruginosa* (ATCC 27853) were maintained on MHA agar plates by inoculation of a single colony on fresh agar plate and overnight incubation at 37°C, every week. The bacteria were kept in glycerol at -80°C as stock culture.

To obtain the overnight cultures, the single colonies of *P. aeruginosa* were inoculated in 4 ml of MHB broth media individually and were incubated at 37°C for 18 hours without shaking. The final bacterial load of 10<sup>6</sup> cfu/ml from overnight culture was inoculated into 400 ml total volume of MHB containing 1.9 mg/ml 3-HPAA or 1.6 mg/ml 4-HBA. The same bacterial load from overnight culture was inoculated into 400 ml total volume of MHB without phenolic acid addition, for control group. All of these were incubated at 37°C for 18 hours without shaking. The obtained cultures were used for total protein isolation.

### **3.2.2. Total Protein Isolation**

Total proteins were isolated from control group and phenolic acid treated groups with the following protocol: The cells were harvested at 10,000 x g for 20 minutes at 4°C. They were washed twice with 20 ml of 0.85% NaCl and centrifuged at 20,000 x g for 20 minutes at 4°C. The pellet was dissolved in PBS (pH 7.4) buffer. Sonication was performed for 9 seconds with 9 seconds of intervals during 15 minutes for control group and 10 minutes for phenolic acid treated groups. The centrifugation was carried out at 20,000 x g for 20 minutes at 4°C and the supernatant was transferred into lo-bind Eppendorf tubes. The samples were kept at -80°C until further usage.

### **3.2.3. Preparation of Peptide Samples**

The ice-cold acetone in 4 times volume of the samples was added on the protein samples and vortexed prior to keeping at -20°C for overnight for acetone precipitation. Then, the protein concentrations were determined by Bradford assay. Since the proteins will be dissolved in resuspension buffer in the next step, bovine serum albumin (BSA) standard was prepared with resuspension buffer (7 M urea and 2 M thiourea in pH 7.8 0.1 M Tris-HCl) and graph was plotted based on the spectrophotometric values of solutions vs concentrations (Appendix C). Then the equation on the graph was used in protein amount determination ( $R^2 > 0.98$ ). After Bradford assay, the concentrations of protein samples were adjusted to 0.4 mg for the LC-ESI-MS/MS analysis. Prior to trypsin addition, in solution digestion was applied to the protein samples as a three-step procedure: DTT (1st step), iodoacetamide (2nd step) and DTT (3rd step). The final concentrations of the reagents were used as 10 mM DTT, 20 mM iodoacetamide and 20 mM DTT in 50 mM Tris-HCl (pH 7.8). In each step, the samples were kept in dark at room temperature for 50 minutes. To clean up the samples, they were transferred into the pre-wetted (with ddH<sub>2</sub>O) 10K cut-off filters centrifuge at 14,000 rpm for 30 minutes. After washing the samples with 50 mM Tris-HCl (pH 7.8), trypsin (in 50 mM Tris-HCl (pH 7.8)) was added in the final concentration of 0.04 µg/ml for each protein sample. The trypsin digestion was carried on overnight at 37°C. The peptide samples were transferred into lo-bind Eppendorf tubes and the volumes of the samples were decreased below 100 µl with speed-vac centrifuge. They were kept at -20°C.

### 3.2.4. LC-ESI-MS/MS (Liquid Chromatography-Electrospray Ionization-Tandem Mass Spectrometry)

High pH reversed-phase chromatography with fraction concatenation was applied to peptide samples as the first step. The volumes of the samples were adjusted to 100 µl by addition of phase A. The phases in fractionation are: Ammonium formate (10 mM) in ddH<sub>2</sub>O (phase A, pH 10) and acetonitrile (90%) and ammonium formate (10 mM) in ddH<sub>2</sub>O (phase B, pH 10). Fractionation of peptide samples were performed with HPLC with high-pH column by LC-solution programme and MALDI-Spotter. The samples were collected in 96-well plates by MALDI-Spotter with 0.05 ml/min flow rate and the fractions were transferred into Eppendorf tubes randomly.

The samples were completely dried by speed-vac centrifuge and zip-tip was applied to the samples before second step (low-pH HPLC) of the analysis. Zip-tip was performed according to the following protocol: 20 µl of Acetonitrile (ACN) (20%) and formic acid (FA) (0.1%) mixture in ddH<sub>2</sub>O was added on each fraction and mixed in ultrasonic bath (15 seconds) and vortexing (5 seconds) alternately for 3 times. The samples were centrifuged at 14,000 rpm for 10 minutes. Zip-tip column (C18) was conditioned by 10 µl of 100% ACN 5 times and 10 µl of 1% FA 5 times. Then the sample was zip-tipped for 10-15 cycles. The column was washed by 10 µl of 1% FA 5 times. The collection of the peptides in column was performed by 50% ACN twice and then by 75% ACN for one time. The collected samples was mixed with 25 µl of 0.1% FA and transferred into the insert tube. It was centrifuged immediately for 5-10 seconds and placed in a vial prior to place in well of HPLC instrument (15 cm low-pH column). The phases of HPLC were: 0.1 % FA in ddH<sub>2</sub>O (phase A) and 0.1 % FA in ACN (phase B). Chromeleon programme was used for HPLC step and after the ion trap electrospraying of these samples by use of Helium gas, the peaks of the samples were collected by LTQ Tune programme. The collected raw data were transferred into MGF format by Proteome Discoverer programme and the data of the fractions were merged by Mass Matrix MS Data File Conversion programme. The reference protein database of *P. aeruginosa* was downloaded from UniProt and saved in MASCOT MS/MS ions programme. MASCOT search of merged data was performed within Uniprot *P. aeruginosa* database. Conditions in MASCOT search were: In fixed modifications, Carbamidomethyl (C); in variable modifications, Oxidation (M); Peptide tolerance, +1.2

Da; MS/MS tolerance, +0.6 Da; peptide charge +2 and +3; instrument, ESI-TRAP; decoy checked. Two biological repeats were analyzed and the data of two independent experiments were combined. All the obtained protein data were compared in Draw Venn Diagram programme (<http://bioinformatics.psb.ugent.be/webtools/Venn/>) to determine the mutual and different proteins between control and phenolic acid treated groups. The functions of the proteins that were undetected or newly detected in the presence of phenolic acids were investigated in UniProt database by using UniProt Retrieve/ID Mapping with protein IDs. As a final step, these proteins were grouped in their functions based on the information in UniProt and the interaction network of the proteins of the groups were determined by STRING software version 10.5 ([https://version-10-5.string-db.org/cgi/input.pl?sessionId=6mlAzREKIVnK&input\\_page\\_show\\_search=on](https://version-10-5.string-db.org/cgi/input.pl?sessionId=6mlAzREKIVnK&input_page_show_search=on)).

### **3.2.5. Validation of Protein Data**

The Real Time-Quantitative PCR (RT-qPCR) was performed for the validation of the protein data on the transcription level. The total RNA isolation of the bacterial cultures, which were subjected to the same conditions of protein isolation protocol, was performed and the total RNA converted to cDNA for RT-qPCR. The primers specific to the housekeeping gene and gene of interest were designed by Primer BLAST software.

#### **3.2.5.1. Isolation of Total RNA and cDNA Preparation**

The isolation of the total RNA from control and 1.9 mg/ml 3-HPAA or 1.4 mg/ml 4-HBA treated *P. aeruginosa* was carried out by GeneJET RNA purification kit (#K0732 Thermo Scientific) according to the manufacturer's instructions with the modifications in the numbers of the washing steps (two times with buffer 1 and three times for buffer 2). The isolated total RNA concentrations, and the 260/280 - 260/230 ratios of the samples were measured by nanodrop and they were kept at -80°C until cDNA preparation.

The cDNA preparation was performed according to the manufacturer's instructions of the kit (# K1622 Thermo RevertAid First Strand cDNA Synthesis Kit). The PCR was carried out in the following conditions: 5 minutes at 25°C; 60 minutes at

42°C and 5 minutes at 70°C. The produced cDNA samples were diluted for 8 times with nuclease free water immediately. They were aliquoted and kept at -20°C until usage.

### **3.2.5.2. Real Time-Quantitative PCR (RT-qPCR)**

The primers which were used in RT-qPCR were designed for 30S ribosomal protein S15 and S12 encoded by *rpsO* and *rpsL* genes, respectively by using the Uniprot. Primer BLAST programme was used for designing the most suitable primers in Refseq database among Pseudomonadales with maximum target size of 200.

The PCR mixture was prepared based on the recommended protocol of SYBR green kit (LightCycler 480 SYBR Green I Master Mix, Roche) with half of the recommended volume. SYBR green master mix (5 µl) was mixed with primers (0.5 µl for each F and R primers from 10x primer solution) and nuclease free water up to 7.5 µl total volume. The mixture was transferred into the 96-well plate and 2.5 µl of appropriate cDNA (about 250 ng for each sample) was added on each wells. The 96-well plate of RT-qPCR was covered by sealing and centrifuged for 2 minutes at 1500 x g. RT-qPCR was performed in the Roche instrument based on the instructions in Roche catalog. The melting temperature was 50°C and the annealing cycles were 40 during the PCR process.

## **3.3. Results and Discussion**

The bacteria require to adapt immediately to the environmental conditions for survival and regulate their cellular proteome under stress conditions (Langklotz et al., 2012). The treatment of *P. aeruginosa* with each phenolic acid result in various changes in the protein profile of the bacteria, as expected. However, besides the changes which might be attributed to the regulation of proteome for adaptation, various changes in the protein profile of vital mechanisms were also detected after phenolic acid treatment. All of these changes were discussed based on the functions of the undetected or newly detected proteins to be able to enlighten the targets of the phenolic acids for antimicrobial effects as well as regulation under stress conditions. Since the phenolic acids showed high antimicrobial effects on *P. aeruginosa*, these results were consistent with our hypothesis that “if growth pattern of the bacteria changes in the presence of

phenolic acids, then; some changes in the proteome of the bacteria would be expected after the treatment with subinhibitory concentrations of them”.

The grouping of protein profiles of *P. aeruginosa* in the presence of 3-HPAA, 4-HBA or the untreated bacteria were presented in Figure 3.1 as a Venn diagram. There are 284 mutual proteins which remain the same in all groups (Figure 3.1, region VII). The names, protein IDs and gene names of these proteins could be found in Appendix D. Throughout the text, the proteins which were only detected in control group will be referred as “undetected proteins” whereas the proteins which were only detected in the phenolic acid treated groups as “newly detected proteins”. The 108 proteins were not detected mutually (Figure 3.1, region V) and 55 mutual proteins were newly detected in the protein profile of *P. aeruginosa* in the presence of the phenolic acids (Figure 3.1, region II). The regions of the Venn diagram for each phenolic acid treatment represents the protein profiles in the following: Proteins that were mutual in control and 3-HPAA treated groups (regions VI and VII); undetected proteins in the presence of 3-HPAA (regions IV and V); newly detected proteins in the presence of 3-HPAA (regions I and II); mutual in control and 4-HBA treated groups (regions IV and VII); undetected proteins in the presence of 4-HBA (regions V and VI); newly detected proteins in the presence of 4-HBA (regions II and III).

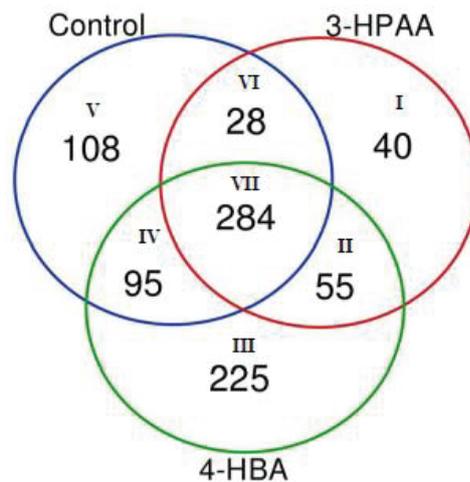

Figure 3.1. The Venn diagram representation of protein profile of *P. aeruginosa* in the presence of 3-HPAA or 4-HBA. The referring of the romen numbers were presented in the text.

### 3.3.1. The Protein Profile in the Presence of 3-HPAA

The results demonstrated that 312 proteins were mutual in control and 3-HPAA treated groups (Figure 3.1; regions VI and VII). On the other hand, 203 proteins were undetected (Figure 3.1; regions IV and V) and 95 proteins were newly detected (Figure 3.1; regions I and II) when the bacteria were treated with 3-HPAA. The proteins which were undetected or newly detected were divided into eight main groups according to their functions in UniProt database and the percentages of these groups were calculated (Figure 3.2). According to their functions, the protein groups were related with DNA; RNA; ribosomes and protein; cell wall and membrane; metabolism; redox and cell homeostasis; virulence and uncharacterized functioned proteins.

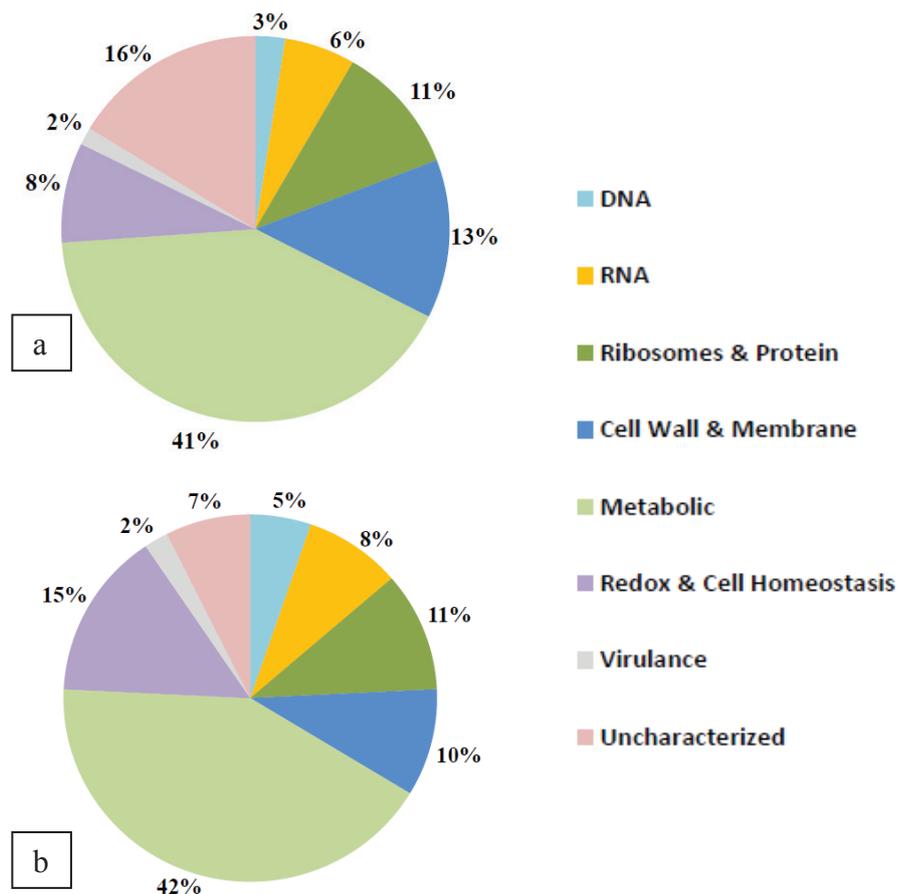

Figure 3.2. The percentages of proteins for each group of function in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins

The percentages demonstrated that undetected proteins displayed 3%, 6%, 11%, 13%, 41%, 8%, 2% and 16% for DNA related, RNA related, ribosomes and protein related, cell wall and membrane related, metabolism related, redox and cell homeostasis related, virulence related and uncharacterized proteins, respectively (Figure 3.2 a). The newly detected proteins showed a similar percentage pattern for the groups of DNA related, RNA related, ribosomes and protein related, cell wall and membrane related, metabolism related, redox and cell homeostasis related, virulence related and uncharacterized proteins with 5%, 8%, 11%, 10%, 42%, 15%, 2% and 7%, respectively (Figure 3.2 b). These results indicated that metabolism related proteins comprised the highest percentages of protein profiles of 3-HPAA treatment. Since various proteins were in function in the general metabolism pathways, these highest percentages were expected. The lowest percentages were determined for the undetected and newly detected virulence-related proteins, which showed that 3-HPAA had a relatively small effect on virulence compared to the other groups of the functions.

### **3.3.1.1. DNA-Related Proteins of 3-HPAA Treatment**

The interaction network of DNA related proteins were determined by STRING database via gene names for undetected proteins, newly detected proteins or both groups in Figures 3.3 a, 3.3 b and 3.3 c, respectively. The profile of DNA related proteins, which were undetected or newly detected, presented the changes in proteins functioned in DNA replication, recombination and DNA repair mechanisms (Tables 3.1 and 3.2).

According to these results, undetected proteins were functioned in DNA replication (DNA topoisomerase 4 subunit B and Vitamin B12-dependent ribonucleotide reductase) and DNA repair (UvrABC system protein A and DNA mismatch repair protein) (Table 3.1). On the other hand, one of the newly detected proteins were functioned in DNA repair (Exodeoxyribonuclease III) which might show the bacteria attempt to repair their DNA by Exodeoxyribonuclease III protein in default of the undetected ones.

When the STRING was applied to undetected and newly detected proteins together, it was demonstrated that the bacteria managed to survive by production of newly detected proteins which interact with undetected proteins, thus, maintaining the vital functions for DNA metabolism (Figure 3.3 c). The proper DNA replication and

repair mechanisms are required for cell survival. If some problems arise in these mechanisms, DNA recombination mechanisms are usually activated in bacteria for maintenance or DNA repair (Sidorenko et al., 2015). The treatment with 3-HPAA caused DNA replication and topological change related proteins as well as nucleotide excision repair and mismatch repair related proteins to be undetected. It might display that 3-HPAA result in DNA damage since these mechanisms had high importance for cell survival.

Three main DNA repair mechanisms exist in organisms which are base excision repair (BER), nucleotide excision repair (NER) and mismatch repair (MMR) (Tark et al., 2008). It could be seen that, the treatment with 3-HPAA might result in the destroy two of these mechanisms; NER and MMR (Table 3.1).

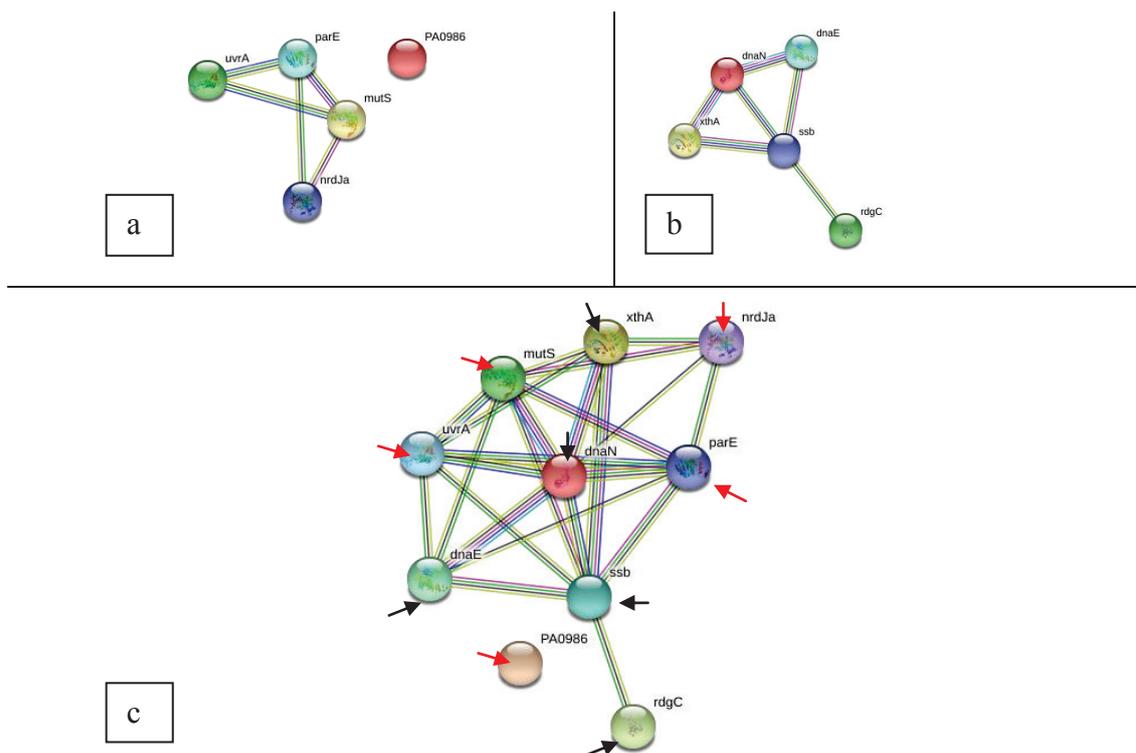

Figure 3.3. String representation of DNA-related proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins c) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

The UvrABC system protein A, which takes role in the initial steps of NER, was undetected after 3-HPAA treatment. The recognition of damaged region of DNA by UvrABC DNA repair mechanism requires the complex of proteins coded by *uvrA*, *uvrB* and *uvrC*. This complex is called UvrABC exonuclease and the initial assembly of it takes place by the binding of UvrA to UvrB. This initial complex searches for the lesion throughout the DNA for finding the damaged region to start the repair with NER (Tark et al., 2008). Since the UvrA protein was not detected in the presence of 3-HPAA, it might be speculated that NER mechanism of *P. aeruginosa* was negatively affected. Since the damage in the NER could be resulted in the accumulation of the mutations, 3-HPAA treatment might have caused the deterioration in the genome of *P. aeruginosa*, thus, inhibition of bacterial growth.

Table 3.1. The undetected proteins related to DNA in the presence of 3-HPAA.

Protein ID	Protein Name	Gene Name	Function
Q9HUJ8	DNA topoisomerase 4 subunit B	parE PA4967	DNA topological change
Q9HT76	Vitamin B12-dependent ribonucleotide reductase	nrdJa PA5497	DNA biosynthetic process, DNA replication
Q9HWG0	UvrABC system protein A	uvrA PA4234	Nucleotide excision repair, SOS response
Q9HY08	DNA mismatch repair protein MutS	mutS PA3620	Mismatch repair
Q9I4Y3	Uncharacterized protein	PA0986	Transposase activity, transposition

Table 3.2. The newly detected proteins related to DNA in the presence of 3-HPAA.

Protein ID	Protein Name	Gene Name	Function
Q9I0T9	Exodeoxyribonuclease III	xthA PA2545	Endonuclease activity, DNA repair
Q9HXZ1	DNA polymerase III subunit alpha	dnaE PA3640	DNA replication
Q9HYX7	Recombination-associated protein RdgC	rdgC PA3263	DNA recombination
Q9I7C4	Beta sliding clamp	dnaN PA0002	DNA strand elongation involved in DNA replication, 3'-5' exonuclease activity, DNA-directed DNA polymerase activity
P40947	Single-stranded DNA-binding protein	ssb PA4232	DNA recombination, DNA repair, DNA replication

Another important protein, MutS, which is a crucial protein functioned in the first steps of MMR mechanism (Monti et al., 2012) was also not detected after 3-HPAA treatment. MMR mechanism is one of the most important repair mechanism aids to maintain the genome integrity in DNA replication (Oliver et al., 2002). Initial recognition of the mismatch lesions in DNA is done by MutS protein after which the other components of the repair mechanism are recruited (Monti et al., 2012). The undetection of this protein in the presence of 3-HPAA might show that 3-HPAA damaged the mismatch repair mechanism of the bacteria. The incapacity of bacteria to repair mismatches may lead an increased mutation rate (Oliver et al., 2002) which might have been in the case of 3-HPAA treatment.

The newly detected proteins in the presence of 3-HPAA were mostly about DNA replication with which these proteins the bacteria attend to continue the proper DNA replication. Exodeoxyribonuclease III, DNA polymerase III subunit alpha, Single-stranded DNA-binding protein and Beta sliding clump not only function in replication, but also have DNA repairing properties. This might demonstrate that the DNA of *P. aeruginosa* was damaged with 3-HPAA application and the bacteria perform DNA repair as well as the replication. The replication machinery of bacteria requires DNA polymerase III holoenzyme for proper replication and proofreading. The holoenzyme has the catalytic DNA polymerase III (Pol III) alpha subunit in its structure and the binding of Pol III with beta sliding clump results in the process of proper replication (Rego et al., 2013). Since these proteins were newly detected, it could be speculated that the bacteria carried out the DNA replication simultaneously with the DNA repair after treated with 3-HPAA.

In addition, “Recombination-associated protein RdgC” was also newly detected. It might demonstrate that *P. aeruginosa* started to use recombination mechanism to protect its genome integrity. Additionally this might show that the bacteria managed to fix DNA damages since recombination also has role in DNA repair by working together with other repair systems (Sidorenko et al., 2014). Although the phenolic compounds are toxic to bacteria in a dose-dependent manner, some bacteria including *Pseudomonas* can consume them below the toxic concentrations (Ghaima et al., 2017). The bacteria may acquire the genes for the degradation of phenolic compounds by horizontal gene transfer via recombination (Tavita et al., 2012). Since the treatment of *P. aeruginosa* resulted in the new detection of “Recombination-associated protein RdgC”, it might

attempt to handle with the damages on its DNA arouse from toxicity of 3-HPAA by recombination.

Therefore, the results indicated that the 3-HPAA treatment might lead serious damages in DNA replication and repair mechanisms which were managed to be fixed by new proteins of replication, repair and recombination mechanisms.

### **3.3.1.2. RNA-Related Proteins of 3-HPAA Treatment**

The application of 3-HPAA resulted in changes in protein profile of *P. aeruginosa* by detection (Figure 3.4. a) and newly detection (Figure 3.4. b) of some RNA-related proteins. The undetected RNA related proteins were generally about the regulation of transcription, RNA polymerase core enzyme binding and tRNA processing (Table 3.3). The newly detected proteins were also functioned in transcriptional regulation in addition to transcription initiation and RNA polymerase transcription activation (Table 3.4). In addition, the interaction network of both groups were demonstrated in Figure 3.4. c which showed that the undetected and newly detected proteins had interactions.

The RNA polymerase sigma-54 factor (RpoN) was undetected while RNA polymerase sigma factor RpoD was newly detected. Although they are both important sigma factors functioned in the control of gene expression, their roles are different. The newly detection of RpoD ( $\sigma^{70}$ ) might show that the bacteria manage to increase the transcription since  $\sigma^{70}$  is the major sigma factor for controlling the expression of many housekeeping genes (Potvin et al., 2008).

The RpoN ( $\sigma^{54}$ ) was shown to have vital roles in motility, nutrient transport, quorum sensing, virulence, production of pilus and flagellum, adhesion and nitrogen assimilation (Potvin et al., 2008). In addition,  $\sigma^{54}$ -dependent promoters exist in *P. aeruginosa* (Buck et al., 2000) so that, the expression from these promoters cannot be made in the absence of  $\sigma^{54}$  (Potvin et al., 2008). Since  $\sigma^{54}$  was not detected when the bacteria was treated with 3-HPAA, the proteins which were expressed dependent to  $\sigma^{54}$  might be not expressed. Surprisingly, the major regulators of the catabolic systems of Pseudomonads for phenolic compounds, DmpR and XylR, are highly homologous to  $\sigma^{54}$ -dependent regulators with many similar structural and mechanistic properties, which activate the degradation of phenolic compounds (Sze et al., 2002). The undetection of

$\sigma^{54}$  might lead to the elevated toxicity of 3-HPAA depending on the reduced function of phenolic catabolism pathways of *P. aeruginosa*. In addition, the reduction in nitrogen assimilation by undetection of  $\sigma^{54}$  as well as the undetection of DNA-binding transcriptional regulator NtrC functioned in nitrogen utilization (Table 3.3) also might cause nitrogen starvation and eventually bacterial growth inhibition.

The phenolic compounds are known to be metal chelators (Singh and Kumar, 2019; Andjelkovic et al., 2006). The treatment with 3-HPAA could result in the chelation of iron in the environment and the bacteria might be under stress because of iron starvation. Ferric uptake regulation protein (Fur) which was undetected in the presence of 3-HPAA (Table 3.3) was functioned in iron limitation and oxidative stress adaptations of bacteria (Pinochet-Barros and Helmann, 2018). The undetection of Fur protein indicated that 3-HPAA presented a change in iron homeostasis of *P. aeruginosa* accompanying with the oxidative stress. Fur proteins are accepted as promising targets of antimicrobial action since they are not found in eukaryotic cells and mandatory for bacterial cell survival and host infection. In addition, the studies which investigated the inactivation of fur genes of pathogenic bacteria including *P. aeruginosa*, resulted in reduced virulence in animal infection models (Mathieu et al., 2016). Since 3-HPAA caused Fur proteins to be undetected, the antimicrobial effect of it might be due to failure of bacteria to adapt iron starvation and oxidative stress.

The tRNA 2-selenouridine/geranyl-2-thiouridine synthase (SelU) which is the enzyme functioned in hydrophobic tRNA modification for geranylated tRNA formation (Wang et al., 2016), was undetected after 3-HPAA treatment. This hydrophobic modification of tRNA is a natural RNA modification and it was discovered in a few bacteria including *P. aeruginosa* (Wang et al., 2016). The geranylation occurs at the wobble position (U34) in the anticodon of lysine, glutamine and glutamic acid (Dumelin et al., 2012) and provides elevated codon recognition fidelity as well as reduced frameshift reading (Sierant et al., 2016). Furthermore, Ribonuclease T, which takes role in tRNA 3'-end processing, was also undetected. The processing of tRNA 3'-end is very important for tRNA biogenesis since it is used as editing and repairing of tRNAs (Rammelt and Rossmanith, 2016). These results indicated that 3-HPAA caused defects in tRNA biogenesis of the bacteria which might lead serious problems of RNA processes. The stringent starvation protein A, which is an important protein in stringent stress response, was undetected after 3-HPAA treatment. As a matter of fact, the

adaptation of bacteria to various conditions can be achieved by sigma factors since they are the key factors of RNA polymerase holoenzyme (Swiecilo and Zych-Wezyk., 2013). The stringent response proteins help functioning of the alternative sigma factors under stress conditions (Swiecilo and Zych-Wezyk., 2013). The undetection of stringent starvation protein A, might restrain the adaptation of bacteria to the environment containing 3-HPAA which aid the inhibition of bacterial growth.

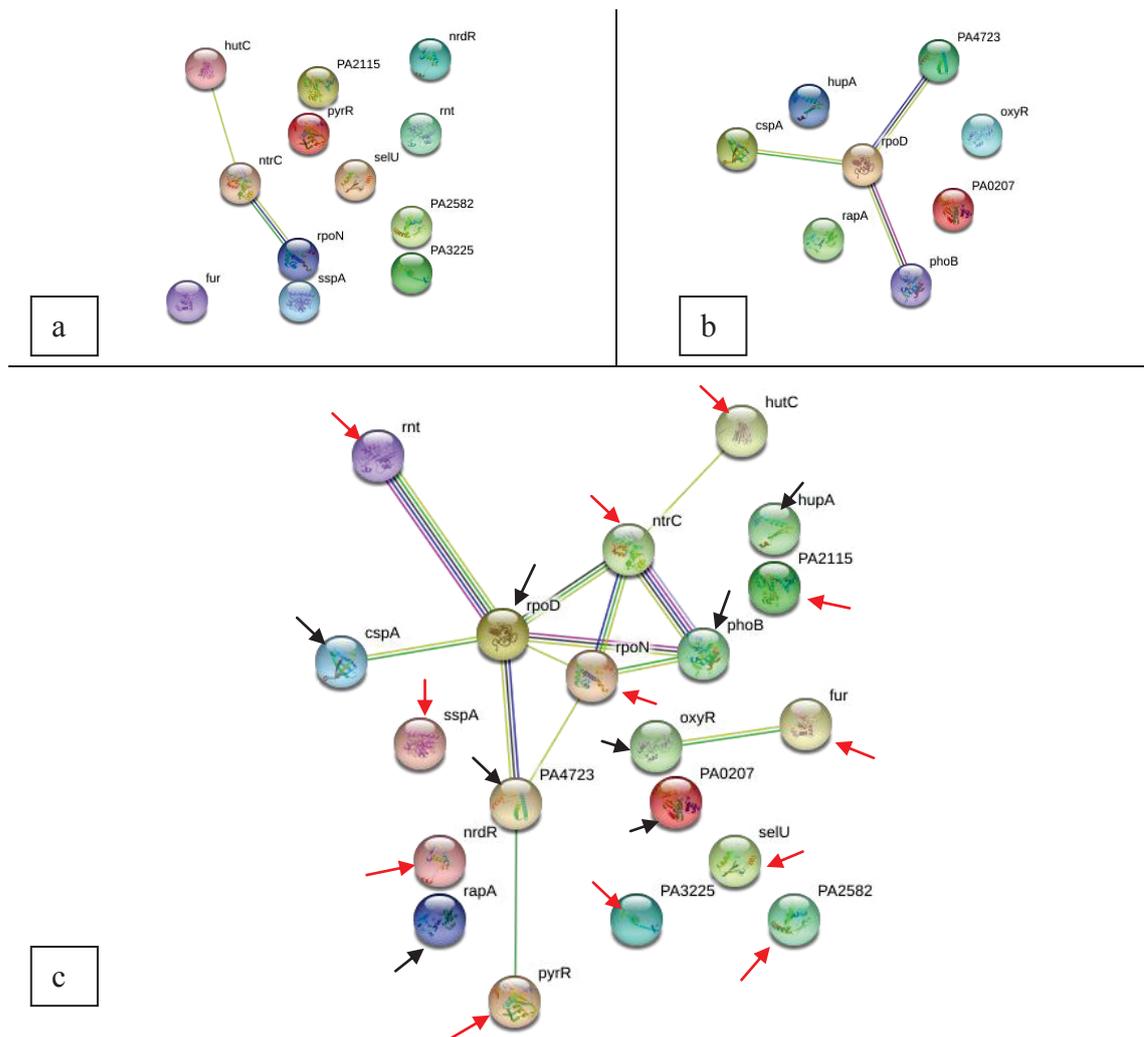

Figure 3.4. String representation of RNA-related proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins c) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

Table 3.3. The undetected proteins related to RNA in the presence of 3-HPAA.

Protein ID	Protein Name	Gene Name	Function
P49988	RNA polymerase sigma-54 factor	rpoN PA4462	Transcription initiation, sigma factor activity
Q9HVV7	Stringent starvation protein A	sspA PA4428	RNA-polymerase core enzyme binding

Q9HU78	Histidine utilization repressor	hutC PA5105	Negative regulation of transcription, histidine catabolic process
Q9HU59	DNA-binding transcriptional regulator NtrC	ntrC PA5125	Nitrogen fixation, regulation of nitrogen utilization, regulation of transcription
Q9HWX1	Transcriptional repressor NrdR	nrdR PA4057	Transcription, negative regulation of oxidoreductase activity,
Q03456	Ferric uptake regulation protein	fur PA4764	Negative regulation of transcription

The major cold shock protein CspA was newly detected which functions in the cell survival of the bacteria in sudden decrease of temperature (Table 3.4). It stabilizes the secondary structures on mRNA occurred by cold temperatures to fix the RNA functionality (Bisht et al., 2014). This might demonstrate that 3-HPAA resulted in the stress conditions as in the cold shock. Therefore *P. aeruginosa* might have used this protein for regaining proper RNA function under stress conditions. The phosphate regulon transcriptional regulatory protein PhoB which was newly detected after 3-HPAA treatment, which is a major protein functions in phosphate limitation of the bacteria (Faure et al., 2013). The regulation of virulence functions of *P. aeruginosa* is controlled by signal transduction pathway PUMA3 when inorganic phosphate limitation exist (Quesada et al., 2016). To be activated, PUMA3 requires not only the phosphate starvation but also PhoB transcription factor (Faure et al., 2013). Since PhoB is the only transcription factor that recognize the inorganic phosphate limitation and activate the other genes (VreA and VreR) of PUMA3 transduction pathway (Quesada et al., 2016),

the new detection of it might present that the bacteria experience the phosphate starvation in the presence of 3-HPAA.

Another stress condition that *P. aeruginosa* experienced under 3-HPAA treatment was the oxidative stress due to newly detection of OxyR. This protein is one of the key transcriptional regulators of oxidative stress defense (Kim et al., 2019). In addition to the oxidative stress response genes (*katA*, *katB*, *ahpB* and *ahpCF*), the *oxyR* gene also regulates the genes function in iron homeostasis, quorum sensing, protein synthesis and oxidative phosphorylation in *P. aeruginosa* (Wei et al., 2012). This might indicate that the bacteria showed various changes in metabolism dependent on the response to the oxidative stress caused by 3-HPAA.

Table 3.4. The newly detected proteins related to RNA in the presence of 3-HPAA.

Protein ID	Protein Name	Gene Name	Function
P95459	Major cold shock protein CspA	cspA PA3266	Regulation of transcription
Q9I6T1	Probable transcriptional regulator	PA0207	Transcription, DNA binding transcription factor activity
P23620	Phosphate regulon transcriptional regulatory protein PhoB	phoB PA5360	Flagellum-dependent swarming motility, phosphate ion transport positive regulation of cellular response to phosphate starvation, transcription

P26480	RNA polymerase sigma factor RpoD	rpoD rpoDA, PA0576	DNA binding transcription factor activity, sigma factor activity, transcription initiation

### 3.3.1.3. Ribosome and Protein-Related Proteins of 3-HPAA Treatment

The results of STRING for undetected and newly detected ribosomes and protein metabolism-related proteins were presented in Figure 3.5 a and b, respectively. The

interactions of all the proteins of these groups were also shown in Figure 3.6. According to these, various changes in t-RNA ligase profile occurred after 3-HPAA treatment. For instance, Glutamine-tRNA ligase and Cysteine-tRNA ligase (Table 3.5) were undetected while Methionine-tRNA ligase, Glutamate-tRNA ligase, Tyrosine-tRNA ligase 2, Isoleucine-tRNA ligase, Phenylalanine-tRNA ligase beta subunit and Probable ATP-binding component of ABC transporter (Valine-tRNA ligase activity) were newly detected (Table 3.6). These show that 3-HPAA showed effect on tRNA ligases, thereby on bacterial protein synthesis. It is clear that tRNA ligases (Aminoacyl-tRNA synthetases; Source: <https://www.uniprot.org/keywords/KW-0030>) are crucial for protein translation in bacteria as they are crucial for translation of all organisms. They are the key components that carry aminoacids to the ribosomes to maintain the growth of peptide chain in translation (Ferro et al., 2018). Such that, the inhibition of processes of tRNA ligases is accepted as one of the important approaches for antimicrobial drug development recently (Ho et al., 2018; Lee et al., 2018). The mechanism of action of the topical antibiotic, which is in use, Mupirocin, depend on the inhibition of isoleucyl-tRNA reversibly in Gram positive bacteria (Parenti et al., 1987). Similarly, the antibiotic purpuromycin which inhibit bacterial translation by making complexes with tRNAs, acts by inhibiting the aminoacylation of tRNAs (Kirillov et al., 1997). Since the exposure of 3-HPAA caused some t-RNA ligases to be undetected, it might affect the growth of *P. aeruginosa* by affecting the tRNA ligase profile, thereby the bacterial protein synthesis.

The 30S ribosomal protein S15 which is crucial for bacterial ribosome structure and translation, was undetected (Table 3.5). Another 30S ribosomal protein, S18 was newly detected (Table 3.6) and according to STRING results, these proteins strongly interact each other (genes: rpsO and rpsL) (Figure 3.6). The prokaryotic ribosomes, on which the proteins are synthesized, consist of 30S small subunit and 50S large subunit which are made up of ribosomal RNAs and proteins (Aseev and Boni, 2011). The small subunit of the prokaryotic ribosome includes one rRNA (16S rRNA), large subunit includes two rRNA (23S and 5S rRNA) subunits and dozens of various ribosomal proteins (Aseev and Boni, 2011). These two main subunits make a complex via intersubunit bridges (Liu and Fredrick, 2016). The protein S15 which directly binds to mRNA (Shajani et al., 2011) is located in Bridge B4 of these bridges, which is required for proper ribosome assembly and translation (Liu and Fredrick, 2016). The binding of

the proteins S6, S18, S11 and S21 is dependent to the protein S15 *in vitro* (Shajani et al., 2011). However, in an *E. coli* strain, the deletion of *rpsO* which encodes for S15, did not prevent the binding of these proteins *in vivo* (Bubunenko et al., 2006). Thus, it could be speculated that even though S15 is a key component for small subunit assembly *in vitro*, there might be some other ribosomal assembly pathways that bacteria could use in the absence of S15 *in vivo* (Shajani et al., 2011). Since S18 protein was newly detected, the alternative assembly of the ribosome might be due to S18 protein. Another alternative of cell survival might be the assembly with the usage of S8 protein (Appendix D) rather than S15. Since S8 protein is another primary protein that binds to 16S rRNA in the same vicinity (Culver, 2003), bacteria might use this protein for proper ribosomal assembly in the absence of protein S15. Since Though Bubunenko et al. indicated that, the mutant bacteria had a diminished 70S ribosomal structure, it was compromised for growth and it had a cold-sensitive phenotype which shows that under non-optimal conditions S15 protein is vital for cell survival (Bubunenko et al., 2006). The undetection of protein S15 in the presence of 3-HPAA which caused an unideal condition might result in the detrimental effects on *P. aeruginosa* by damaging the ribosomal assembly. In addition, the cell survival of the bacteria might be due to the usage of subinhibitory concentrations of 3-HPAA for the protein isolation. It could be speculated that the bacteriocidal effect of higher concentration might be related to the bacteria not affording the proper ribosomal assembly in the absence of S15.

The antimicrobial effect of many antibiotics are due to targeting the ribosomal subunits. One of the main targets of antibiotics (i.e., gentamicin, kanamycin) is small ribosomal subunit of the bacteria (Sutcliffe, 2005). The 3-HPAA could be accepted as a promising antimicrobial agent since it displayed a change in small ribosomal subunit of *P. aeruginosa*. In addition to the effects on the small subunit structure, 3-HPAA also displayed effects on the large subunit assembly and RNA structure by undetection of ATP-dependent RNA helicase DeaD and Ribosomal RNA large subunit methyltransferase J. The large subunit is mainly related to production of polypeptide in translation (Aseev and Boni, 2011). Thus, 3-HPAA affected the translation by undetection of these large subunit proteins as well as the undetection of proteins related to translational initiation (Translation initiation factor IF-1), translational fidelity (Glutamyl-tRNA(Gln) amidotransferase subunit C) and rRNA (guanine-N7)-methylation (Ribosomal RNA small subunit methyltransferase G) (Table 3.5).

Besides these, the effect of 3-HPAA on protein metabolism could be noticed by undetection of proteins about homopolymerization and tetramerization, Chromosome partitioning protein Spo0J and Protein-export protein SecB, respectively (Table 3.5). Undetection of aminopeptidases, Cytosol aminopeptidase and Aminopeptidase N also showed the effect of 3-HPAA on protein metabolism (Table 3.5) and the STRING results showed that the Aminopeptidase N (gene pepN) were related with protein SecB (gene secB) (Figure 3.6). In addition, D-ala-D-ala-carboxypeptidase functioned in carboxypeptidase activity (gene dacC) was newly detected (Table 3.6). This might present the changes in metabolism of bacteria since aminopeptidase activity was diminished and carboxypeptidase activity occurred in the presence of 3-HPAA. Aminopeptidases are the enzymes that function in the cleavage of N-terminal of the peptides or proteins (Nandan and Nampoothri, 2017) which determine the structure and function them. A precursor protein which has an amino terminal signal sequence is recognized by the molecular chaperone SecB and it was determined that the inactivation of SecB caused defects in translocation of some precursor proteins and in growth of *E. coli* (Driessen, 2001). The undetection of SecB and Aminopeptidase N might lead the defects in process and translocation of the proteins with N-terminal signal sequence which might result in serious consequences in *P. aeruginosa* metabolism after treatment with 3-HPAA. On the other hand, the new detected protein, D-ala-D-ala-carboxypeptidase belongs to the carboxypeptidase enzymes. They are responsible for the removal of the terminal D-alanine from muramyl pentapeptide in the synthesis of peptidoglycan layer which is the protective component of bacterial cell wall (Ghosh et al., 2008; Meyer et al., 2018). An energy-saving property of the bacteria is the usage of the carboxypeptidases and endopeptidase together for recycling of the peptidoglycan subunits which were broken down or released in the media during the cell growth (Templin et al., 1999; Meyer et al., 2018).

Although in the rich media the bacteria build the peptidoglycan layer again (Meyer et al., 2018), it was shown that the blocking of this recycling could result in the autolysis of *E. coli* (Templin et al., 1999). New detection of D-ala-D-ala-carboxypeptidase might indicate that the bacteria manage to repair or reuse the peptidoglycan layer products which might be obtained from cell wall damage as well as the obligation of energy-saving in the media including 3-HPAA. All of these results demonstrated that the treatment of *P. aeruginosa* with 3-HPAA resulted in significant

changes in ribosome structure, translation and protein metabolism in addition to clues for membrane damage of the bacteria. The undetection of mentioned proteins could result in the inhibition of the bacterial growth.

### 3.3.1.4. Cell Wall and Membrane-Related Proteins of 3-HPAA Treatment

The application of 3-HPAA on *P. aeruginosa* resulted in the significant changes in the cell wall and membrane of the bacteria with the undetection (Figure 3.7 a) or newly detection (Figure 3.7 b) of important proteins interacted with each other (Figure 3.8). The undetected proteins were functioned in membrane composition and structure, cell division, Type IV-pilus biogenesis, flagellum and chemotaxis, and phosphorelay transduction system (Table 3.7). On the other hand, the newly detected proteins were related to cell envelope organization, cell division, flagellum and chemotaxis (Table 3.8). The cell envelope, which is characteristic to Gram negative bacteria, is the covering structure of bacterial cell that consists of two membranes with a thin peptidoglycan layer in between (Stinnett et al., 1973). It functions as the protective component (Meyer et al., 2018), basis for cell division, motility and signal transduction of bacterial cell. The detection of vital changes in the protein profile of this structure might indicate major changes in bacterial metabolism after 3-HPAA treatment.

The proteins about composition and structure of the membrane, Membrane protein insertase YidC, Signal recognition particle receptor FtsY, Rod shape-determining protein MreB and many other integral components of the membrane were undetected. The protein YidC is functioned in the insertion and integration of the small membrane proteins into the membrane by co-working with Sec proteins (Dalbey et al., 2011) as well as proteolytic degradation of membrane or cytoplasmic proteins (Kiefer and Kuhn, 2018). Another membrane related protein, FtsY, is one of the responsible proteins for the targeting of nascent polypeptide chains to the membrane which means it aids the transfer of the newly formed proteins to the cytoplasmic region of the membrane (Dalbey et al., 2011). Since these proteins were not detected after 3-HPAA exposure, the membrane protein targeting and insertion into the membrane in *P. aeruginosa* might be damaged because of 3-HPAA. The rod-shape of *P. aeruginosa* is regulated by MreB protein filaments which bind to the inner membrane and regulate the insertion of cell wall precursors (Shi et al., 2017). Surprisingly, the undetection of MreB was not resulted in the defect of rod shape of *P. aeruginosa* in SEM micrographs (Figure 2.3 c and d). Although MreB is accepted as an important component for rod shape of the bacteria, the bacteria might use an alternative way to overcome the undetection of MreB since the MreB function is adjustable and related mostly to its partner proteins, MreC, RodZ, FtsZ, RodA, PBPs, MurF, MraY, and MurG (Gurrola et al., 2017). Though, treatment of 3-HPAA forced *P. aeruginosa* to change the cell envelope structure for survival.

Besides this, outer membrane protein assembly factor BamD and Probable carboxyl-terminal protease, which are related to the cell envelope organization, and Cell division coordinator CpoB, which is functioned in FtsZ dependent cytokinesis, were newly detected. The lipoprotein BamD is one of the essential components of Bam complex which is vital for outer membrane biogenesis (Mori et al., 2012). Cell division coordinator CpoB is an important protein that controls peptidoglycan synthesis and outer membrane construction which result in the maintenance of integrity of cell envelope (Gray et al., 2015). It might show that the cell wall especially outer membrane was highly defected and repair was carried out by carboxyl-terminal protease and BamD for maintenance of proper cell division. In addition, the proteins which take vital roles in cell cycle and division, Tol-Pal system protein TolQ and ATP-dependent zinc metalloprotease FtsH were undetected. The Tol-Pal system is an important system of

Gram negative bacteria for outer membrane integrity continuance (Dubuisson et al., 2005). The Tol-Pal system, which is structurally conserved among Gram negative bacteria (Sturgis, 2001), consists of seven genes in *Pseudomonas*, orf1, tolQ, tolR, tolA, tolB, oprL and orf2 (Llamas et al., 2003) and the damages occur in the outer membrane if the mutations are generated in the genes of Tol-Pal system proteins (Dubuisson et al., 2005). Among these proteins, TolQ is undetected after 3-HPAA exposure which resulted in the defect in Tol-Pal system of *P. aeruginosa*, thereby the cell envelope integrity.

The undetection of another important protein, FtsH, might also result in the damage in the cell envelope structure and regulation of cell metabolism. FtsH is one of the proteases that control the regulation of the cell metabolism immediately in the presence of an environmental stress and it is universally conserved among prokaryotes (Langklotz et al., 2012). Although the proteases are found in cytoplasm, FtsH is the only one protease that is attached to the inner membrane (Narberhaus et al., 2009). It is responsible of quality control of the membrane proteins (Langklotz et al., 2012) and post-translation of transcription factors and enzymes (Narberhaus et al., 2009). As an example, the post translational regulation of RpoH ( $\sigma^{32}$ ) is mostly carried out with FtsH (Langklotz et al., 2012) as well as the regulation of RpoN ( $\sigma^{54}$ ) (Carmona and de Lorenzo, 1999) in *E. coli*. The undetection of FtsH might result in the problems in the regulation of these transcription factors, thus, transcription of *P. aeruginosa* might be defected. Since it was shown that RpoN was also undetected after 3-HPAA treatment (Table 3.3), it could be speculated that 3-HPAA treatment generated serious changes in the regulation of transcription in addition to the defects in the cell envelope structure of *P. aeruginosa*. The FtsH was presented to degrade FtsZ, which is the main protein functioned in the initiation of the septum formation in bacterial cell division, *in vitro* (Srinivasan et al., 2008). However, as far as we know, the studies which show the reason or result of this process *in vivo* are not exist. Though, it could be speculated that the undetection of FtsH resulted in the cell division changes in *P. aeruginosa* besides its aforementioned effects. Briefly, the cell envelope is a natural protection barrier against many unfavorable environmental conditions such as presence of antimicrobial agents and the undetection of some of the crucial proteins of cell envelope demonstrated that 3-HPAA affected the bacterial cell wall integrity and cell division as an antimicrobial agent. Relatedly, the invagination line in the surfaces of the bacteria in the presence of

3-HPAA, which were presented in SEM micrographs (Figure 2.3 c and d), might be due to the aforementioned undetected proteins.

The type4 pili components were also undetected in the presence of 3-HPAA. The type4 pili (fimbriae) flexible filaments found in the poles of *P. aeruginosa* (Kazmierczak et al., 2006) and one of the main virulence factors which aids the initiation and maintenance of the infections (Huang et al., 2003) and biofilm formation (Jain et al., 2017). The main functions of T4 pili were presented as the attachment to various surfaces such as metals, glass, plastics and various host tissues (Giltner et al., 2012) in a calcium dependent manner (Johnson et al., 2011) by twitching motility (Carter et al., 2017). Twitching motility, which is also crucial for biofilm formation, is a flagellum-independent type of motility and occurs by stretching and retractions of the pili (Huang et al., 2003; Carter et al., 2017). The T4 pili type that is found in *P. aeruginosa* is T4a pilus (T4aP) (Giltner et al., 2012). The protein PilY1, is a T4aP machinery protein (Carter et al., 2017) and is required for surface adherence and manipulation of the host (Giltner et al., 2012). PilQ, PilM (Carter et al., 2017; Jain et al., 2017) and PilG (Darzins, 1993) are another proteins of T4aP machinery which are functioned as the structural components of the pili. The protein FimX is functioned for proper twitching motility and required for biogenesis and assembly of type IV pili (Huang et al., 2003; Jain et al., 2017). On the other hand, B-type flagellin which is a virulence factor functioned in flagellum-dependent motility and flagellum organization (Bakht azad et al., 2018) was newly detected. This might show that the bacteria shifted the motility type from pilus-dependent to flagellum-dependent. The bacteria uses the flagellum not only in virulence (Bakht azad et al., 2018), but also for the movement in chemotaxis (Chaban et al., 2015) through which it can recognize the environmental conditions and decide their direction. The bacteria uses phosphorylated CheY protein in rotation of the flagellum in both cases of escaping form an environment or going towards an attractant (Chaban et al., 2015). Therefore, new detection of flagellin B protein might indicate that the bacteria manage to travel away because of 3-HPAA. However, undetection of CheY protein could either show that the flagellum-dependent motility of the bacteria is damaged or it used an alternative way rather than CheY usage. Another newly detected protein, Protein PilJ which is functioned in chemotaxis, also presented that the bacteria manage to escape from the inconvenient conditions of the environment in the presence of 3-HPAA.

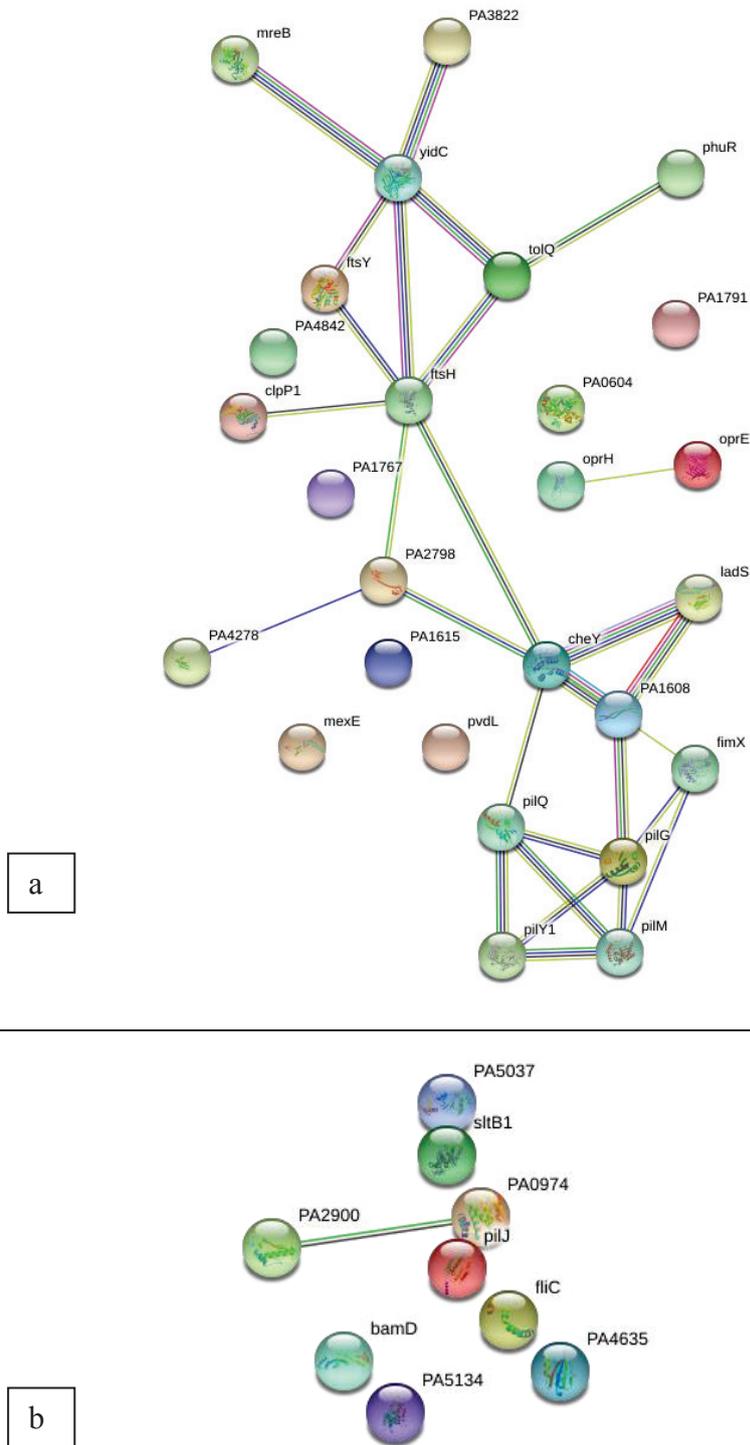

Figure 3.7. String representation of cell wall and membrane-related proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins

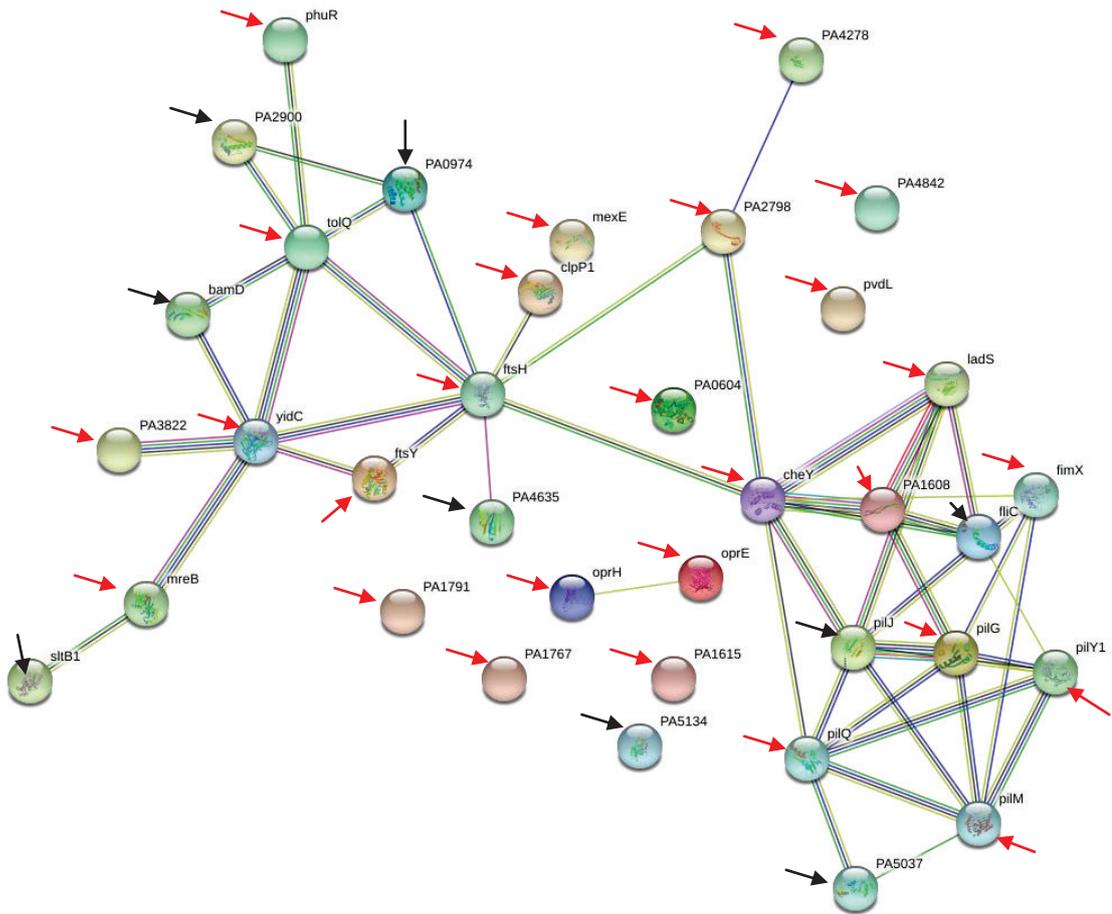

Figure 3.8. String representation of cell wall and membrane-related undetected and newly detected proteins in the presence of 3-HPAA. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins black arrows).

In another point of view, it could be speculated that the disuse of Type 4 fimbrial motility (twitching) and usage of flagellar motility (planktonic, swimming) (Kazmierczak et al., 2015) under 3-HPAA applied conditions, might show the bacteria tried to produce flagella instead of the pili and planktonic motility is preferred as an adaptation process. In addition, since biofilm formation, which was related to higher virulence, was diminished by disuse of the pili, 3-HPAA might decrease the virulence of *P. aeruginosa*. Thus, the treatment of *P. aeruginosa* with 3-HPAA resulted in serious damages and changes in the cell wall and membrane structure and function which might lead the inhibition of bacterial growth.

### 3.3.1.5. Metabolism-Related Proteins of 3-HPAA Treatment

The treatment with 3-HPAA resulted in various changes in the metabolism of *P. aeruginosa* at the proteomic level by which undetected or newly detected proteins (Figures 3.9, 3.10 and 3.11). Since the bacteria must adapt to the environment in the presence of non-optimal conditions such as the presence of a toxic substance (Langklotz et al., 2012), it could be speculated that the changes in the protein profile of the metabolic processes might aid the adaptation. Relatedly, the serious changes/adaptations in the particular metabolic systems of the bacteria after 3-HPAA exposure might give clues about the targets of its antimicrobial effect.

According to results of this study, various undetected and newly detected proteins functioned in amino acid biosynthesis were found (Tables 3.9 and 3.10). For

example, the proteins related to biosyntheses of alanine, lysine, leucine, cysteine and aromatic amino acid as well as arginine catabolic process were undetected and lysine, alanine, histidine, glutamine, serine and glycine metabolism related proteins were newly detected which indicate the regulations in the amino acid metabolism. In addition, Porin D, functioned in amino acid transport, and Aminopeptidase P were another undetected proteins related to amino acid biosynthesis. Aminopeptidase P (PepP) is a member of aminopeptidases P (APPro) family and functions in the removal of N-terminal residue of the polypeptides a second residue of proline (Peng et al., 2017). Since it is highly conserved among *Pseudomonads* and played role in the virulence of the bacteria, it is accepted as a promising antimicrobial target (Peng et al., 2017). The undetection of this protein indicates that it might be one of the targets for antimicrobial effect of 3-HPAA. Gram negative bacteria possess a resistance mechanism in which they decrease membrane permeability for antibiotic by reducing the porins (Serra et al., 2019). The undetected porin, Porin D, was presented as a channel protein for uptake of  $\beta$ -lactam antibiotics (Khatua et al., 2014). Thus, it might be speculated that *P. aeruginosa* did intentionally not express the Porin D to protect itself from 3-HPAA such in a way of resistance against  $\beta$ -lactam antibiotics. On the other hand, this might also show that there is a problem with the transport systems and outer membrane protein profile.

Nicotinate phosphoribosyltransferase 1, which is functioned in NAD biosynthesis, was not detected after 3-HPAA treatment, thus the NAD recycling of *P. aeruginosa* might be defected. Since NAD is the vital element of metabolic pathways of enzymes functioned in redox or non-redox processes, NAD depletion might cause a fatal result in the cell regardless of being prokaryotic or eukaryotic (Huang et al., 2009). The undetection of Nicotinate phosphoribosyltransferase 1 might indicate that the bacteria are under serious stress. Additionally, the problem in NAD biosynthesis might lead to serious damages in the energy metabolism of the bacteria. However the cell survival maintained in the presence of subinhibitory concentrations of 3-HPAA. Therefore, it could be speculated that *P. aeruginosa* handled the undetection of NAD 1 by using alternative partners of this protein for biosynthesis of NAD (Okon et al., 2017).

The 3-HPAA treatment resulted in the undetection of the proteins functioned in pyocyanin and phenazine biosyntheses. Many members of the genus *Pseudomonas* secrete extracellular pigments (El-fouyl et al., 2015). The *P. aeruginosa* culture

demonstrates a distinct greenish-blue color which arise from the mixture of blue color of the bacteria and yellow color of the media (Rada and Leto, 2013). The pigment called pyocyanin produced by *P. aeruginosa* is the reason for the blue color (Rada and Leto, 2013). It synthesizes the pyocyanin pigment called phenazine, which is the water-soluble extracellular pigment possessing a heterocyclic structure, is capable of produce reactive oxygen species and toxic to other microorganisms for microbial competition as well as to eukaryotes (Dietrich et al., 2006; El-fouyl et al., 2015, Rada and Leto, 2013) Relatedly, the new antimicrobial agents arise from phenazine were presented (Borrero et al., 2014). In addition, phenazine was presented as one of the three main molecules in quorum sensing mechanism of *P. aeruginosa* which is the system of bacteria to communicate and behave in a synchronized way as well as increasing the virulence (Dietrich et al., 2006, Ugurlu et al., 2016). Thus, quorum sensing targeted antimicrobial agents are accepted as promising new strategies against pathogenicity (Lu et al., 2018, Ugurlu et al., 2016) and the agents that inhibit the production of phenazine gets attention in this manner.

In our study, it was morphologically demonstrated that the greenish-blue color of the bacterial cultures disappeared when 3-HPAA was applied (Figure 2.2 a). At the proteomic level, this color decrease could be attributed to the undetection of the proteins which take role in phenazine production (5-methylphenazine-1-carboxylate 1-monooxygenase, Phenazine biosynthesis protein PhzB1, Phenazine biosynthesis protein PhzE). Thereby, it is clear 3-HPAA reduces the virulence of *P. aeruginosa* by preventing the phenazine production which makes it a favorable antimicrobial agent candidate.

The changes in the profile of lipid metabolism related proteins showed that the proteins functioned in fatty acid beta oxidation were undetected while lipid biosynthesis proteins as well as phosphate transport and phospholipase synthesis were newly detected. Thus, the treatment of *P. aeruginosa* with 3-HPAA resulted in elevated lipid biosynthesis and reduced fatty acid degradation which might indicate the effort of the bacteria to maintain the integrity of cell envelope in the presence of 3-HPAA.

All these changes in the metabolism-related proteins indicate that the bacteria not only attempt to adapt to the environmental conditions by changing the metabolic pathway preferences to survive, but also they were seriously affected via damages in virulence factors and quorum sensing components.

### 3.3.1.6. Redox and Cell Homeostasis-Related Proteins of 3-HPAA Treatment

Superoxide and hydrogen peroxide are the examples of reactive oxygen species (ROS) which are required to be removed to maintain the cell homeostasis and survival (Kamariah et al., 2015). The redox and cell homeostasis related protein profile of *P. aeruginosa* presented various changes (Figure 3.12 a and b) related to each other (Figure 3.12 c) which indicated that 3-HPAA presence in the environment resulted in serious stress response. For example, the Lon protease, alkyl hydroperoxide reductase subunit F, glutathione reductase and superoxide dismutase [Mn] were the proteins, which are responsible for stress response, were undetected after 3-HPAA treatment (Table 3.11). On the other hand, glutathione peroxidase, organic hydroperoxide resistance protein, peptide methionine sulfoxide reductase MsrA and probable major facilitator superfamily (MFS) transporter which functioned in oxidoreductase activity were newly detected. Thus, 3-HPAA application resulted in serious oxidative stress on *P. aeruginosa*.

Lon protease is an intracellular protease that has roles in response to stress such as DNA damage, antibiotic resistance and virulence, swarming motility and biofilm

formation (Fernandez et al., 2016). In addition, the protein that regulate Lon protease, Hfq (Fernandez et al., 2016) (Table 3.5) was also undetected after 3-HPAA treatment. Thus, 3-HPAA result in not only damage of Lon protease mediated processes but also the regulation of Lon protease itself.

Alkyl hydroperoxide reductase is an enzyme functioned in reduction of peroxides (Kamariah et al., 2015) as well as superoxide dismutase [Mn] in superoxides (Iiyama et al., 2007). The superoxide and hydrogen peroxide are the toxic substances for the cell via damaging the DNA and membranes (Hasset et al., 1996). These proteins were undetected in the presence of 3-HPAA. In addition, Fur protein, which is related to proper superoxide dismutase activity (Hasset et al., 1996) and iron homeostasis, was also undetected (Table 3.3, Section 3.3.1.2). Thus, the redox and iron homeostasis might be damaged with 3-HPAA application.

Glutathione reductase was undetected while glutathione peroxidase was newly detected. Since both are functioned in oxidative stress response, it could be speculated that *P. aeruginosa* manage to respond the oxidative stress caused by 3-HPAA. Since the glutathione is a major response to oxidative stress and adaptation, the changes in the glutathione metabolism related proteins demonstrates that the bacteria regulated the adaptation for oxidative stress caused by 3-HPAA. Glutathione reductase is an evolutionary conserved protein and highly homologous in both prokaryotes and eukaryotes (Smirnova and Oktyabrsky, 2005) which functions in the reduction of highly toxic glutathione disulfide to glutathione by using NADPH to protect the cell from oxidative stress during the cell survival (Smirnova and Oktyabrsky, 2005). Thus, the undetection of this protein might affect the redox homeostasis regulation and led the new detection of Glutathione peroxidase which is another protein that takes role in reduction in hydroperoxides from glutathione (Atichartpongkul et al., 2016).

Peptide methionine sulfoxide reductase MsrA is one of the main enzymes which is induced in the stress caused by chemicals such as phenolic compounds (Tamburro et al., 2001). Under the oxidative stress conditions the reactive oxygen species cause oxidation of the methionine residues leading the reduction of the protein function. MsrA protein found in various tissues and organisms can repair these proteins by reducing the oxidized methionine back to methionine, thereby the function of these proteins are regained (Mintz et al., 2002, John et al., 2001). In addition, Spermidine/putrescine import ATP-binding protein PotA, biosynthetic arginine decarboxylase and polyamine

aminopropyltransferase 1 functioned in spermidine/putrescine metabolism were also newly detected after 3-HPAA treatment (Table 3.12). Spermidine and putrescine are main polyamines in bacteria which are functioned in cell viability, pathogenesis, antibiotic resistance and protecting the DNA from oxidative damage (Johnson et al., 2011). They also play roles in signaling and regulation against stress conditions caused by reactive oxygen species (ROS), heat, UV, acid and osmotic pressure as well as in production and function of porins in outer membrane (Bandounas et al., 2011). Therefore, the new detection of transport and biosynthesis proteins related to putrescine and spermidine might show that the bacteria give responses to stress conditions caused by 3-HPAA treatment in a similar way of oxidative stress.

Table 3.11. The undetected proteins in the presence of 3-HPAA functioned in redox and cell homeostasis.

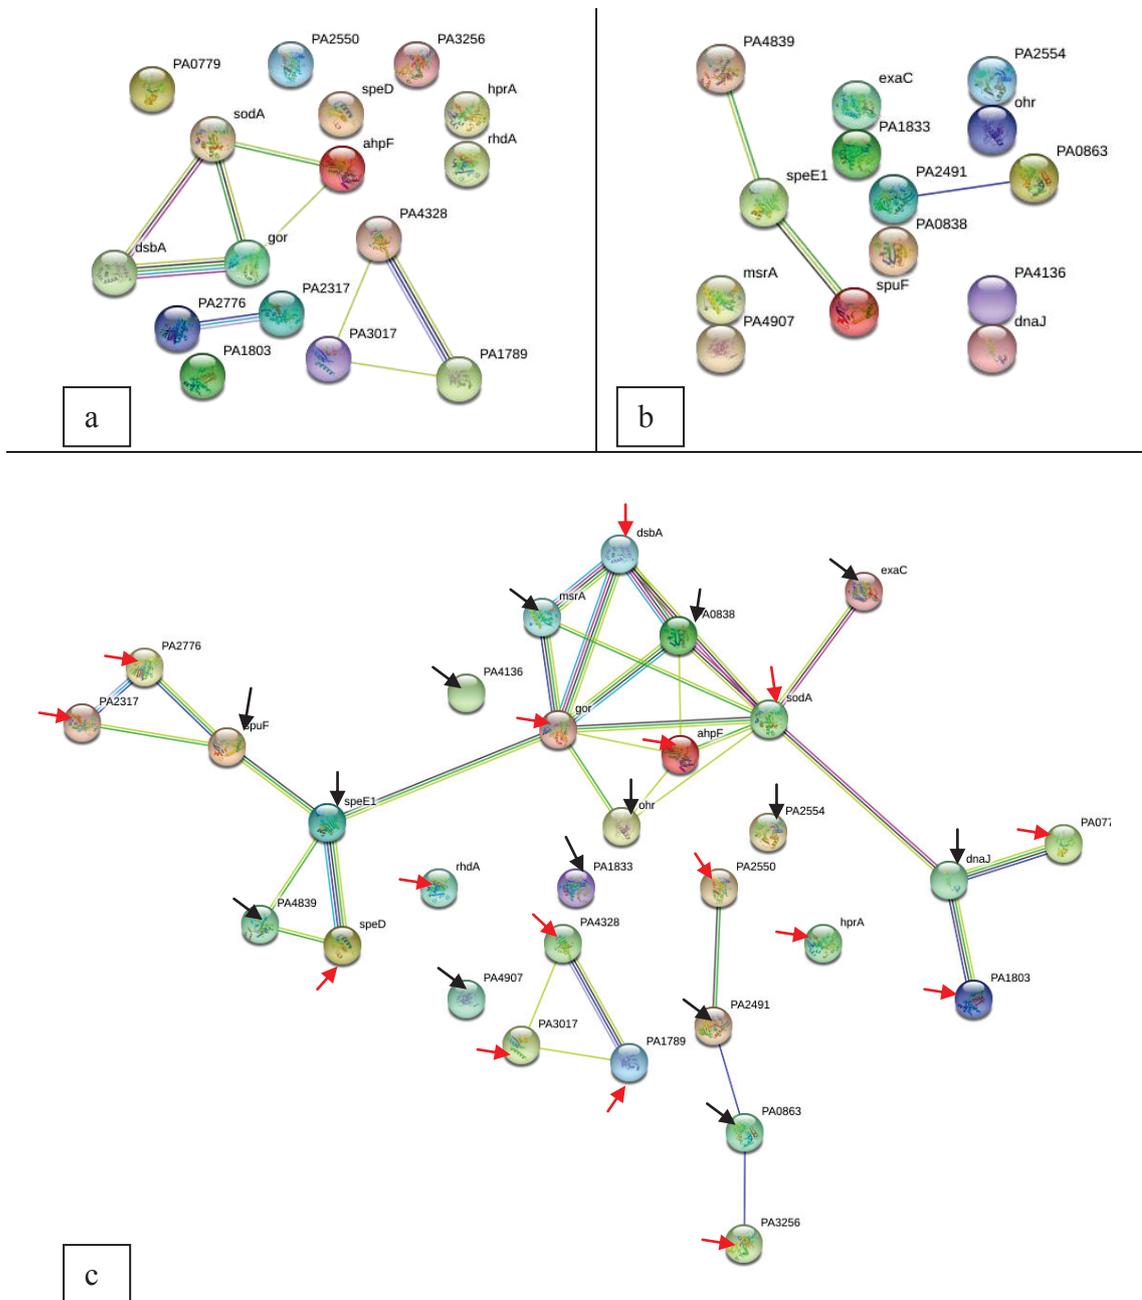

Figure 3.12. String representation of redox and cell homeostasis-related proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins c) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### 3.3.1.7. Virulence-Related Proteins of 3-HPAA Treatment

The undetected proteins in the presence of 3-HPAA which were related to virulence were presented in Figure 3.13 a, while newly detected ones were in 3.13 b. They had no interactions as it could be seen in Figure 3.13 c.

Phosphomannomutase/phosphoglucomutase protein (Protein ID: P26276; Gene name: algC PA5322) was multi-functional with its roles in alginic acid biosynthetic process, GDP-alpha-D-mannose biosynthetic process, lipopolysaccharide core region biosynthetic process, O antigen biosynthetic process and pathogenicity. One of the results which is significant was undetection of this protein as it is functioned in alginate production in *P. aeruginosa* which is a exopolysaccharide layer aids the mucoid morphology by production of alginate layer (Darzins et al., 1985).

This layer acts as a protection for bacteria against host immune defenses and antibiotics as well as functioning in the attachment of the bacteria to the host cells (Glonti et al., 2010). Disappearance of these proteins after 3-HPAA application might cause a decrease in pathogenicity of *P. aeruginosa* by resulting a phenotype vulnerable to host immune system cells and antibiotics. On the other hand, the uncharacterized protein PA1579 (Protein ID: Q9I3D8; Gene name: PA1579) which might have a role in interaction of the bacterium with animal cells was newly detected as well as other uncharacterized protein (Protein ID: Q9HVG7; Gene name: PA4624) which functioned in single-species biofilm formation. These results might indicate that the bacteria manage to maintain the virulence properties in the absence of the undetected phosphomannomutase/phosphoglucomutase protein.

The other undetected proteins, cyclic AMP receptor-like protein (Protein ID: P55222; gene name: vfr PA0652) and uncharacterized PhzA/B-like protein PA3332 (Protein ID: Q9HYR3; Gene name: PA3332) were functioned in pathogenesis and antibiotic biosynthesis, respectively. The undetection of these proteins suggest that the virulence of *P. aeruginosa* could be decreased with 3-HPAA treatment.

### 3.3.1.8. Uncharacterized Proteins of 3-HPAA Treatment

Various uncharacterized proteins were presented in Figure 3.14 a and b. The most significant profile change for these proteins were the undetection of PA0083,

PA0084 and PA0086 which were strongly interacted each other (Figure 3.14 c). According to the protein BLAST results, these proteins might be Type VI secretion system contractile sheath small subunit, Type VI secretion system contractile sheath large subunit and tetratricopeptide repeat protein for PA0083, PA0084 and PA0086, respectively (Table 3.13). The bacteria possess various mechanisms to interact each other in their niche in a contact-dependent manner to communicate or compete (Basler et al., 2013). Type VI secretion system (T6SS) is one of the widely presented mechanism for the competition of the Gram negative bacteria by secretion of the proteins in adjacent cell.

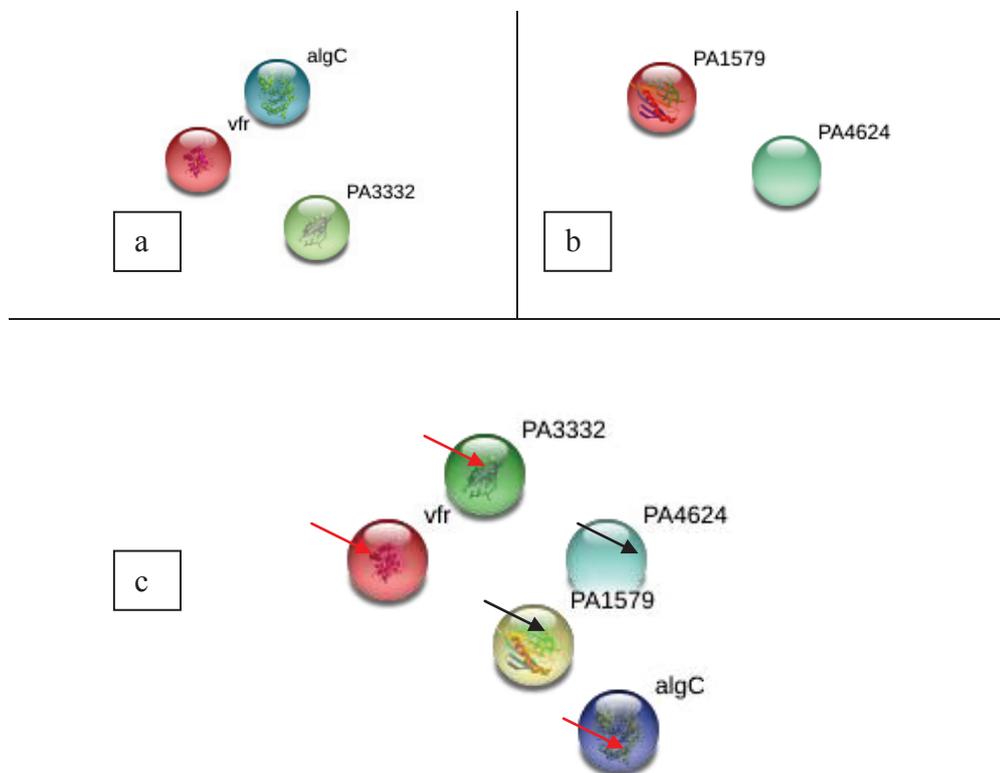

Figure 3.13. String representation of virulence-related proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins c) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

A contractile sheath similar to T4 phage, but in an inverted structure, is used by the bacteria (Russel et al., 2012; Salih et al., 2018). This system is not only used for dispelling the bacteria in vicinity but also used for secretion of toxic effector proteins into eukaryotic cells. Thus, it has a virulence related property for Gram negative pathogenic bacteria including *P. aeruginosa* and may be a promising target for new antimicrobial agents (Salomon and Orth, 2015; Salih et al., 2018). The most striking function of this system was presented as its role in horizontal gene transfer. This system secretes nucleases, pore-forming toxins and hydrolyses to the target bacterial cell and after the death of this cell, the genes of the dead bacteria are taken by the bacteria which secreted the T6SS effector proteins in the first place (Salomon and Orth, 2015). The bacteria which possess T6SS target, lyse and kill the other bacteria possessing T6SS regardless of their species to gain new genes from those (Ringel et al., 2017). However, *P. aeruginosa* do not kill the bacteria which do not contain T6SS. This might indicate that *P. aeruginosa* compete with the ones which could be dangerous to them. In addition, since these bacteria are strong enough to survive in the environment with their “useful” genes than the bacteria without T6SS, they prefer to gain new genes from T6SS positive bacteria (Ringel et al., 2017). The apparatus of T6SS consists of three parts: the membrane complex, the baseplate, and the sheath-tube complex (Ringel et al., 2017). Since the activity of T6SS mostly depends upon the assembly and contraction of sheath part (Salih et al., 2018), the undetection of large and small subunit proteins of contractile sheath might result in the defect of T6SS. Other undetected protein, tetratricopeptide repeat protein, was important for the stability of exporting process of secretions from cell membrane (Whitney and Howell, 2013; Mejias et al., 2019). Thus, the bacterial virulence, competing property and horizontal gene transfer properties of *P. aeruginosa* were diminished by 3-HPAA treatment.

RidA family protein PA5303 was undetected while RidA family protein PA5339 was newly detected which have interaction to each other. RidA, which was named as YjgF previously, is an important protein for metabolite damage repair and presented as an imine diaminase that protect certain enzymes from damage such as repairing specifically inactivation of pyridoxal 5' phosphate dependent enzymes (Hogde-Hanson and Downs, 2017; de Crecy-Lagard et al., 2018). The changes in the members of this family demonstrated that *P. aeruginosa* manage to fix the enzyme damages caused by 3-HPAA.

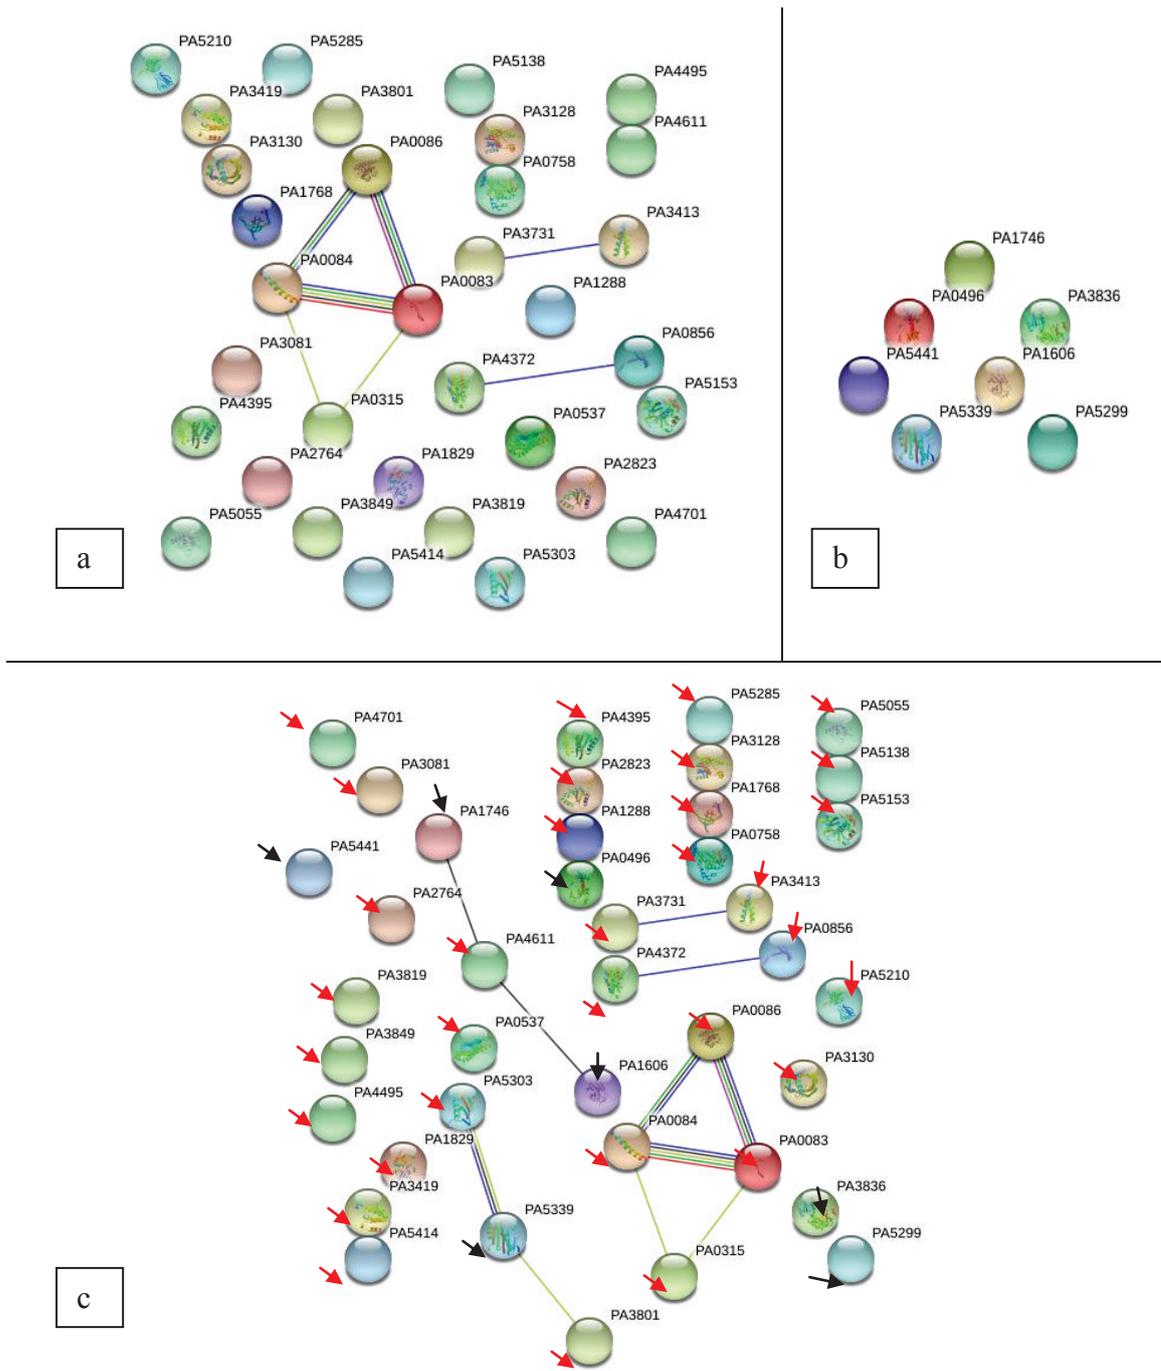

Figure 3.14. String representation of uncharacterized proteins in the presence of 3-HPAA. a) Undetected proteins b) Newly detected proteins c) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

Table 3.13. The undetected proteins in the presence of 3-HPAA which are uncharacterized.

### 3.3.2. The Protein Profile in the Presence of 4-HBA

The results showed that 379 proteins were mutual in control and 4-HBA treated groups (Figure 3.1; regions IV and VII). Number of undetected proteins were 136 (Figure 3.1; regions V and VI) and number of newly detected proteins were 280 (Figure 3.1; regions II and III) after the treatment with 4-HBA.

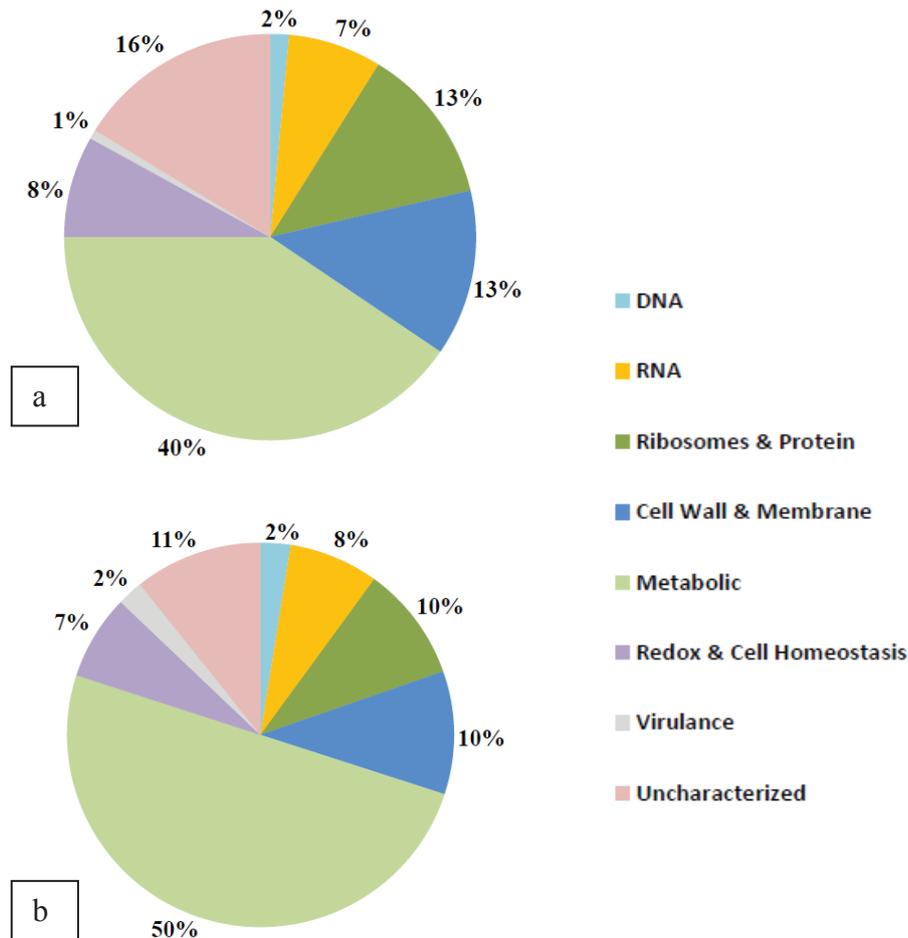

Figure 3.15. The percentages of proteins for each group of function in the presence of 4-HBA. a) Undetected proteins b) Newly detected proteins

The undetected and newly detected proteins were separated according to their functions in UniProt database into eight main groups and their percentages were calculated (Figure 3.20). The protein groups were related with DNA; RNA; ribosomes and protein; cell wall and membrane; metabolism; redox and cell homeostasis; virulence and uncharacterized functioned proteins based on their functions. The undetected proteins in groups of DNA, RNA, ribosomes and protein, cell wall and membrane, metabolism, redox and cell homeostasis, virulence related and uncharacterized proteins showed 2%, 7%, 13%, 13%, 40%, 8%, 1% and 16%, respectively (Figure 3.15 a). The same order of groups, DNA, RNA, ribosomes and protein, cell wall and membrane,

metabolism, redox and cell homeostasis, virulence related and uncharacterized proteins, displayed 2%, 8%, 10%, 10%, 50%, 7%, 2% and 11% for newly detected proteins (Figure 3.15 b). According to these, the metabolism related proteins showed the highest percentages in both undetected and newly detected protein groups. The percentage of newly detected metabolism related proteins percentage was 50% while the undetected proteins' was 40% which showed that 4-HBA treatment result in the production of new proteins more than undetection.

Though, metabolism related proteins show the highest percentage since the general metabolism pathways include various proteins. The virulence related proteins displayed the lowest percentages for both undetected and newly detected proteins. Thus, it could be speculated that the virulence of the bacteria was seldomly affected by 4-HBA treatment.

### **3.3.2.1. DNA-Related Proteins of 4-HBA Treatment**

The STRING database was used to visualize the interaction network of DNA related proteins via gene names. The network of undetected proteins were presented in Figure 3.16 a and of newly detected proteins were in Figure 3.16 b. The complete interaction network of these proteins were demonstrated in Figure 3.16 c in means of undetection and newly detection. In addition, the functions of the undetected proteins and newly detected proteins were shown in Tables 3.15 and 3.16, respectively.

The results demonstrated that the only two proteins related to DNA were undetected after 4-HBA treatment. The most significant result was the undetection of DNA polymerase I which is a key component in DNA replication and repair (Table 3.15). This enzyme is one of the vital enzymes for DNA replication. Since the bacteria survived, the undetection of it might be due to the limitation of LC-ESI-MS/MS method which might detect the proteins up to a level based on ESI conditions. Still, the undetection of this enzyme might demonstrate a significant decrease of it and might show serious defect in DNA replication and repair of the bacteria. DNA polymerase I protein was found in interaction with the proteins related to DNA replication, repair and recombination which were among the newly detected ones (Figure 3.16 and Table 3.16). This might show that the bacteria manage to maintain the DNA replication and repair with these proteins in the absence of DNA polymerase I enzyme. The replication

and repair mechanisms are vital for cell survival, it could be discussed that 4-HBA resulted in important changes in processes related to DNA metabolism. Recombination related proteins, recombination-associated protein RdgC, integration host factor subunit alpha, integration host factor subunit beta and single-stranded DNA-binding protein were newly detected (Figure 3.16 and Table 3.16). Since the bacteria start to activate the DNA recombination mechanisms when replication and repair mechanisms had problems (Sidorenko et al., 2015), *P. aeruginosa* could newly produce these proteins to start recombination for proper replication and repair of DNA. Additionally, bacteria can use recombination for horizontal gene transfer to deal with the toxicity of phenolic compounds (Tavita et al., 2012). The newly detected recombination associated proteins might demonstrate that the bacteria attempt to protect the DNA from damage caused by 4-HBA by recombination. Therefore, the results indicated that the 4-HBA application might lead the changes in DNA replication and cause problems in DNA metabolism of *P. aeruginosa*. The problems arose from undetected proteins might be overcome with the newly detected proteins function in replication, repair and recombination mechanisms.

### 3.3.2.2. RNA-Related Proteins of 4-HBA Treatment

The interaction network of undetected proteins (Figure 3.17 a), newly detected proteins (Figure 3.17 b) and the interaction of those to each other (Figure 3. 18) were determined by STRING. These results showed that, tRNA-specific 2-thiouridylase MnmA protein was undetected while Poly(A) polymerase I and tRNA(Ile)-lysine synthase were newly detected which have strong interactions. The tRNA-specific 2-thiouridylase MnmA protein is functioned in tRNA wobble position uridine thiolation and tRNA binding. This protein is a thiouridylase for uridine modification in bacteria which senses sulfur atom and combine with it *in vivo* for the modification of tRNAs (Shigi, 2018). It is conserved in evolutionary process and functions specifically on lysine, glutamic acid and glycine tRNAs (Armengod et al., 2014). Since this protein is vital for the thiouridine modification in bacteria (Black and Santos, 2015) and the posttranslational modifications of tRNAs are crucial for the precise translation, the undetection of MnmA protein might result in defects in translation. Hence, the thiouridylation of tRNAs were diminished in the absence of MnmA leading the unrecognition of proper codon by tRNA. The newly detected proteins related to tRNA processing might be used for the maintenance of the translation by carrying out the tRNA modification processes. For example, the protein tRNA(Ile)-lysine synthase has strong interactions with MnmA protein and it functioned in the modification of tRNA (Ile) by ligating lysedine nucleoside to the cytidine at the wobble position (Numata, 2015) for the production of isoleucine specific tRNA (Nakanishi et al., 2009). The bacteria might manage to continue the translation by fixing the problems that arouse during the tRNA processing by newly detected proteins for compensating the conformation of the subsequent protein. The Poly(A) polymerase I which was also newly detected, is functioned in mRNA polyadenylation as well as rRNA and tRNA processing. Although the Poly(A) polymerase I was partially purified and characterized in 1962, the polyadenylation of RNA in prokaryotes was underestimated. Nowadays, the importance of polyadenylation in prokaryotes are presented in RNA turnover (recycling of RNA) since the polyadenylated mRNAs are protected from exonucleotic degradation. Additionally, it is speculated that the Poly(A) polymerase I has a role in quality-control of target defective tRNAs to exonuclease processes (Hajnsdorf and

Kaberdin, 2018). Thus, new detection of Poly(A) polymerase I might be due to quality control of tRNAs to determine the defective ones caused by 4-HBA exposure.

In addition, stringent starvation protein A was undetected and ribosome-binding ATPase YchF, which has interaction with this protein, was newly detected. Stringent stress response is functioned in the usage of alternative sigma factors in RNA polymerase holoenzyme for the adaptation to stress conditions (Swiecilo and Zych-Wezyk., 2013). Thus, the adaptation control of the bacteria in stress conditions might be diminished in the presence of 4-HBA since stringent starvation protein A was not detected. The newly detected ribosome-binding ATPase YchF is functioned in virulence, various cellular processes and stress responses including DNA repair and oxidative stress response (Hannemann et al., 2016). It could be speculated that the bacteria experienced a significant stress in the presence of 4-HBA. They manage to fight against DNA damage and especially the oxidative stress.

The new detection of the phosphate regulon transcriptional regulatory protein PhoB might show that 4-HBA application might result in the phosphate starvation in *P. aeruginosa*. This protein has a vital role in phosphate limitation responses of the bacteria (Faure et al., 2013). The genes of signal transduction pathway PUMA3 (VreA and VreR ) which is used in limited phosphate conditions, is activated by PhoB (Quesada et al., 2016; Faure et al., 2013). In addition to phosphate starvation, the bacteria might also have nitrogen starvation, since the DNA-binding transcriptional regulator NtrC functioned in nitrogen utilization was undetected (Table 3.17).

OxyR, which is one of the main transcriptional regulators of oxidative stress response (Kim et al., 2019), was newly detected after 4-HBA treatment. Thus, it could be speculated that 4-HBA activated the oxidative stress response of *P. aeruginosa*. Since OxyR has roles in iron homeostasis, quorum sensing, protein synthesis and oxidative phosphorylation (Wei et al., 2012), the new detection of OxyR showed that various changes occurred in *P. aeruginosa* metabolism with 4-HBA application. To handle these nutrient limiting and stress conditions, the bacteria might manage to maintain the transcription by newly detection of RpoD ( $\sigma^{70}$ ) as well as many other proteins (Table 3.18). Since RpoD is the main sigma factor controlling various housekeeping genes (Potvin et al., 2008) bacteria might try to adapt and survive to the stress conditions arouse by 4-HBA application by increasing the transcription of these housekeeping genes.

### 3.3.2.3. Ribosome and Protein-Related Proteins of 4-HBA Treatment

The 4-HBA treatment showed undetection (Figure 3.19 a) and newly detection protein profiles (Table 3.19 b) whose interactions were demonstrated in Figure 3.20. The undetection or new detection of t-RNA ligases were presented after 4-HBA treatment: Phenylalanine-tRNA ligase alpha subunit and glycine-tRNA ligase alpha subunit were undetected (Table 3.19) while methionine-tRNA ligase, valine-tRNA ligase, histidine-tRNA ligase, glutamate-tRNA ligase, tyrosine-tRNA ligase 2,

threonine-tRNA ligase, phenylalanine-tRNA ligase beta subunit and isoleucine-tRNA ligase were newly detected (Table 3.20). The changes of tRNA ligases after 4-HBA exposure indicated the bacteria make modifications in their protein translation since the transport of amino acids to the ribosomes are carried out mainly by tRNA ligases (Ferro et al., 2018). In addition, the approach of targeting tRNA ligases is a compelling concept in the antimicrobial agent development (Ho et al., 2018; Lee et al., 2018). Thus, the undetection of some tRNA ligases might show that one of the targets of 4-HBA for antimicrobial effect, might be tRNA ligases.

Another important point was the undetection of many small or large subunit components of ribosome after 4-HBA exposure (Table 3.19 and 3.20). Since in 3-HPAA treatment only led the undetection of one small subunit (S15) (Table 3.5) and new detection of one small subunit (S18) (Table 3.6), it might be speculated that 4-HBA resulted in more detrimental defects on ribosome structure and assembly than 3-HPAA did. The undetected ribosome-related proteins were; 30S ribosomal proteins S15, S11, S2, small ribosomal subunit biogenesis GTPase RsgA, ribosomal RNA small subunit methyltransferase G, ribosomal RNA large subunit methyltransferase J and ATP-dependent RNA helicase DeaD (has functions in ribosomal large subunit assembly).

On the other hand, 30S ribosomal protein S18, ribosomal RNA small subunit methyltransferase H, 50S ribosomal protein L23, ribosomal RNA large subunit methyltransferase K/L and ribosomal large subunit pseudouridine synthase D were newly detected.

According to these results, it is clear that 4-HBA mostly targeted the small subunit components and the bacteria began to produce different small and large subunit components to compensate the defects in the ribosome structure and assembly to maintain proper translation. Thus, 4-HBA affected the protein translation via damaging the ribosome not only by changing the small and large subunit components but also by changing the proteins related to translational initiation such as the undetection of translation initiation factor IF-1 and methyltransferases.

Since the aminopeptidases determine the structure and function of the proteins by cleaving the N-terminal (Nandan and Nampoothri, 2017), the changes in these proteins might indicate the significant changes in the protein structure and function, thereby the whole metabolism. SecB which was undetected while SecA was newly detected after 4-HBA treatment.

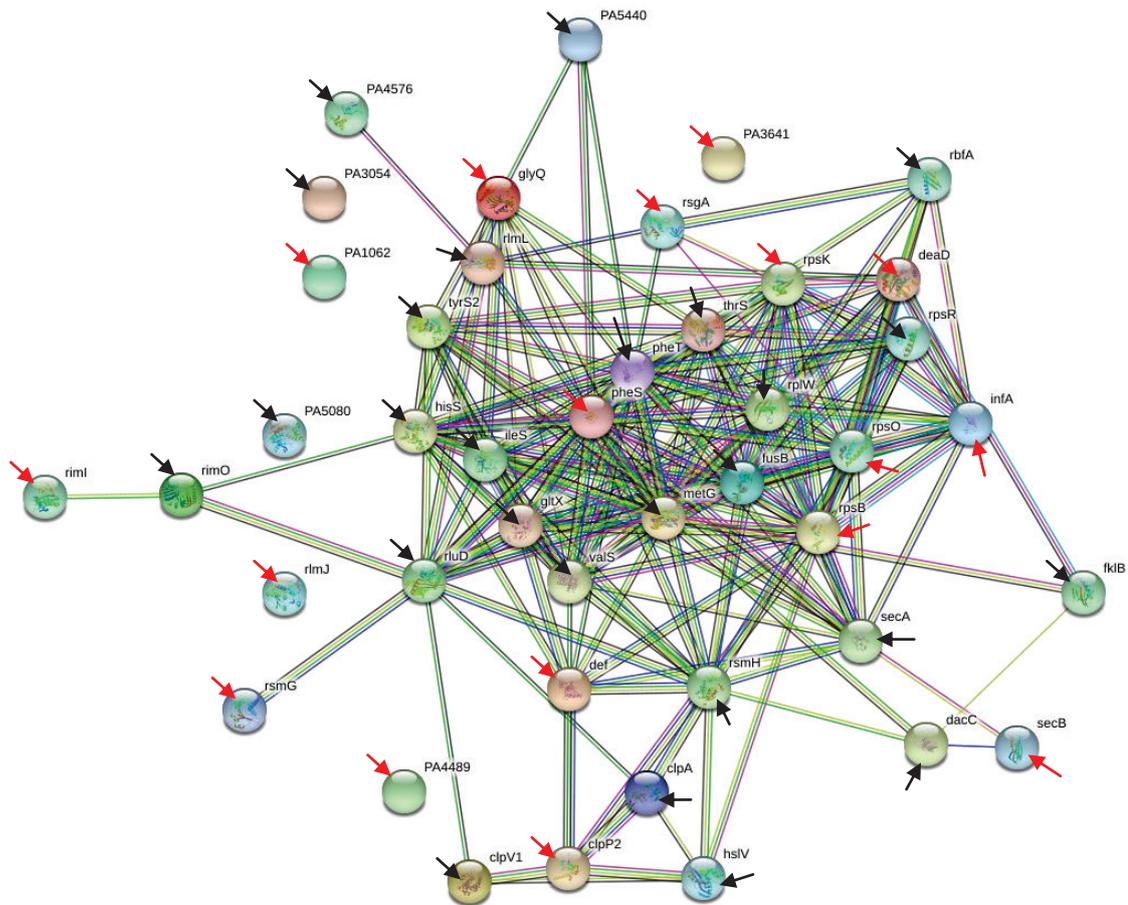

Figure 3.20. String representation of ribosomes and protein-related undetected and newly detected proteins in the presence of 4-HBA. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

The translocation of preproteins with N-terminal signal across the cell membrane is performed by Sec complex (Krishnan et al., 2009). SecA is the ATPase unit of the translocation complex while SecB is the soluble cytosolic protein which recognizes the N-terminal signal of preproteins to direct them to SecA (Driessen et al., 2001). The undetection of SecB indicated a serious damage on the Sec complex which might lead detrimental defects in bacterial protein metabolism.

Various endopeptidases and carboxypeptidases were newly detected while endopeptidase inhibitor Alpha-2-macroglobulin homolog was undetected after 4-HBA treatment similarly to the results of 3-HPAA treatment. The bacteria uses

carboxypeptidases and endopeptidase together for peptidoglycan units recycling as energy-saving rather than producing them from the scratch (Templin et al., 1999; Meyer et al., 2018). The recycling is crucial for the cell viability, such that, inhibition of this process results in autolysis of *E. coli* (Templin et al., 1999). The undetection of endopeptidase inhibitor and new detection of various endopeptidases were noticed in the presence of 4-HBA. In addition, the D-ala-D-ala-carboxypeptidase that cleaves the terminal D-alanine from muramyl pentapeptide was also newly detected which functions in the production of peptidoglycan layer of the bacteria (Ghosh et al., 2008; Meyer et al., 2018). These results might indicate a serious damage in the cell envelope and the bacteria increased the recycling process to repair the peptidoglycan layer by reusing the peptidoglycan units came from membrane damage. This stress might result in the reduction of the bacterial growth in the case of 4-HBA exposure.

#### **3.3.2.4. Cell Wall and Membrane-Related Proteins of 4-HBA Treatment**

The undetected proteins in the presence of 4-HBA were demonstrated in Figure 3.21 a and newly detected ones were in 3.21 b. According to interaction network of these proteins (Figure 3.22), the undetected protein CheY which is functioned in flagellum-dependent cell motility, chemotaxis and positive regulation of single-species biofilm formation was undetected (Table 3.21) while B-type flagellin (FliC) functioned in flagellum-dependent cell motility, bacterial-type flagellum organization was newly detected (Table 3.22).

Since both interacted proteins had roles in flagellum-dependent motility, the undetection of CheY might demonstrate a defect in this system. This protein is used for flagellum rotations in motility for the escape from the undesirable environmental conditions (Chaban et al., 2015). The newly detected protein B-type flagellin is also functioned in flagellum-dependent motility and flagellum organization (Bakht azad et al., 2018). Hence, the bacteria managed to escape the toxic conditions caused by 4-HBA by continuing the flagellum-dependent motility. Although the protein Type IV pilus biogenesis factor PilY1 was undetected, other proteins related to pilus formation, PilV and PilF, which were functioned in pilus assembly, were newly detected. This might

show that 4-HBA resulted in the damage in pilus formation and the bacteria maintained this process by other related proteins.

The profile of main proteins for cell division, Fts proteins, was changed in the presence of 4-HBA. The proteins FtsH and FtsY were undetected while FtsZ was newly detected.

The FtsZ protein is the main protein in the cell division process of the bacteria since it is functioned in the initiation of the septum (Srinivasan et al., 2008). The new detection of it might be due to the bacteria intent to maintain the cell division in the undetection of FtsH and FtsY. Among these proteins, FtsH is functioned in the regulation of the cell metabolism after an environmental stress, quality control of the membrane proteins (Langklotz et al., 2012) as well as posttranslation of various transcription factors and enzymes (Narberhaus et al., 2009).

Another crucial process, targeting the nascent polypeptide chains to the membrane for transferring the new proteins across the membrane is achieved by FtsY (Dalbey et al., 2011) which was also undetected as well as YidC protein which takes roles in the small protein insertion into the membrane in coordination with Sec proteins (Dalbey et al., 2011) and proteolytic cleavage of the membrane or cytoplasmic proteins (Kiefer and Kuhn, 2018). The undetection of these proteins might show that 4-HBA application resulted in serious defects in the bacterial cell membrane structure and integrity which would lead to bacterial death, eventually.

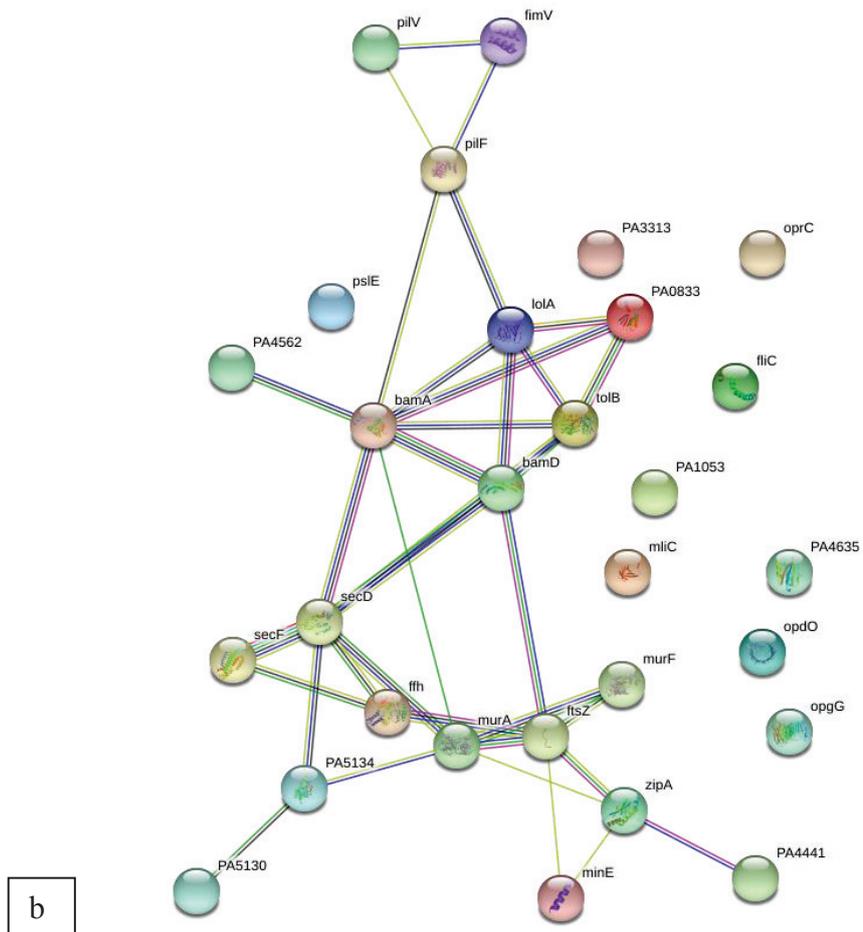

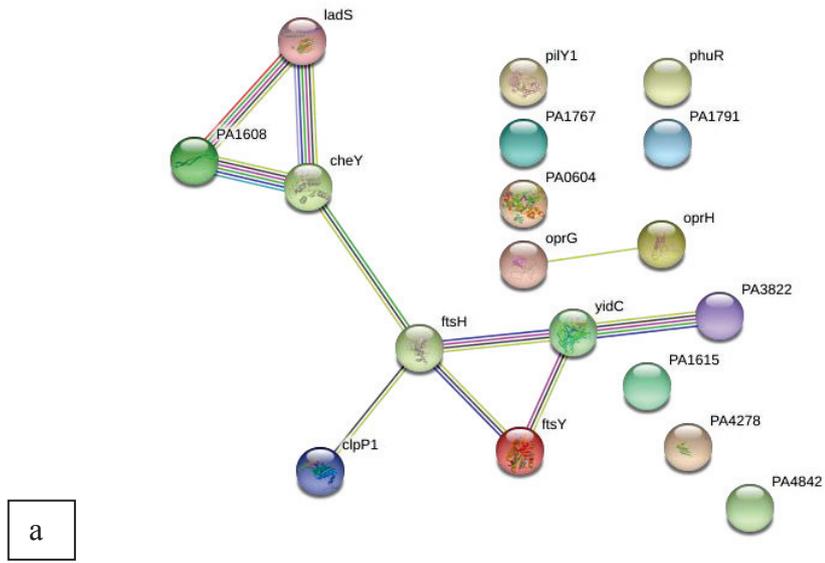

Figure 3.21. String representation of cell wall and membrane-related proteins in the presence of 4-HBA. a) Undetected proteins b) Newly detected proteins

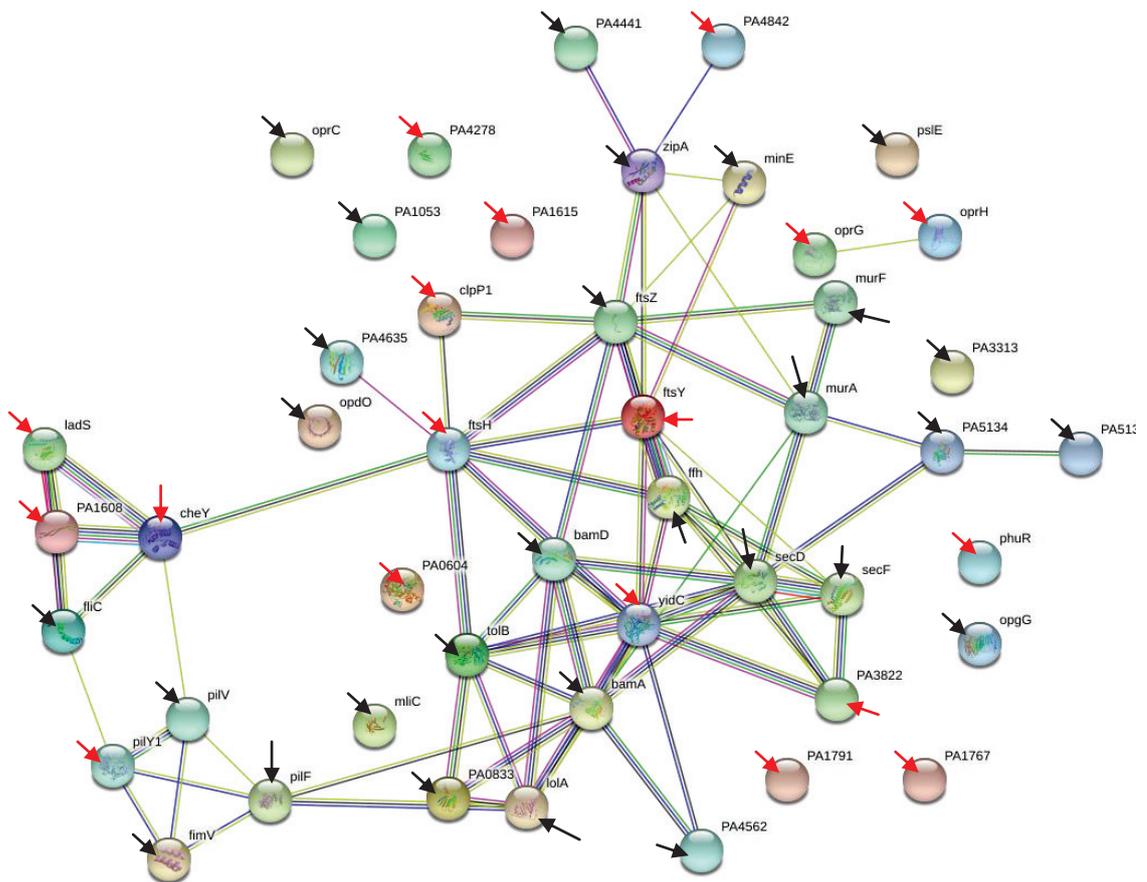

Figure 3.22. String representation of cell wall and membrane-related undetected and newly detected proteins in the presence of 4-HBA. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

Table 3.21. The undetected proteins in the presence of 4-HBA functioned in cell wall and membrane.

Q9I2X2	Uncharacterized protein	PA1767	Transmembrane protein

On the other hand, SecD, SecF, BamA, BamD TolA and TolB, which had interactions with YidC were newly detected. Sec complex is functioned in the transfer of preproteins possessing N-terminal signal through the membrane (Krishnan et al., 2009). SecDFyajC complex is one of the complexes that is involved in the Sec complex and is required for the proper insertion of new proteins into the membrane (Dalbey et al., 2011) and Tol-Pal complex, which includes TolA and TolB, is required for outer membrane integrity of Gram negative bacteria (Dubuisson et al., 2005). Similarly, BamA and BamD proteins had roles in cell envelope organization and cell assembly. Thus, new detection of these proteins might be due to continue the cell wall integrity

and structure caused by 4-HBA. Thus, protein targetting, membrane insertion, cell division and membrane integrity of *P. aeruginosa* were seriously affected by 4-HBA exposure. In addition, these damaged were determined in SEM images of the bacteria as a collapse line on the bacteria surfaces after 4-HBA treatment (Figure 2.3 e and f) which visually demonstrated the serious damage of 4-HBA on cell envelope.

Table 3.22. The newly detected proteins in the presence of 4-HBA functioned in cell wall and membrane.

### 3.3.2.5. Metabolism-Related Proteins of 4-HBA Treatment

The 4-HBA exposure resulted in various metabolic changes. Since the bacteria are in the adaptation period to environmental conditions, the undetection of proteins (Figure 3.23) and newly detected ones (Figure 3.24) with various interactions (Figure 3.25) were expected. In addition, these changes might indicate the potential targets of 4-HBA for the antimicrobial effect. For instance, the proteins functioned in lipid

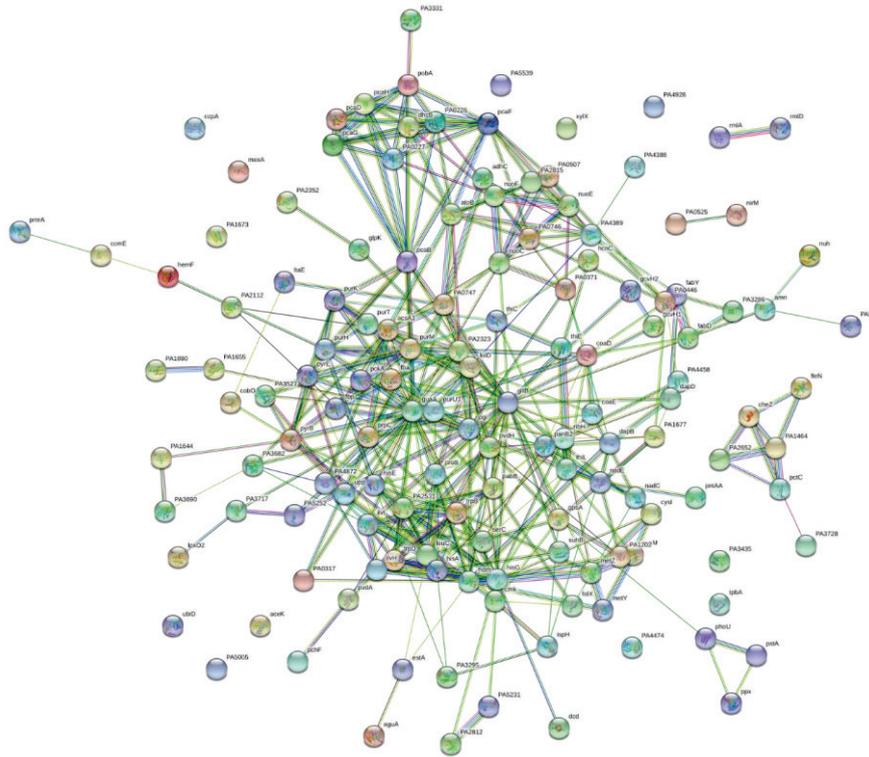

Figure 3.24. String representation of metabolism-related newly detected proteins in the presence of 4-HBA.

The pyoverdine proteins (Pvd) were demonstrated to have important roles in iron uptake (Drehe et al., 2018) and showed a changing profile in the presence of 4-HBA which might be due to iron limitations. Since iron and sulfate are crucial for cell survival, it might be speculated that 4-HBA exposure resulted in iron and sulfate starvation which might be lethal for bacteria in higher degrees. In addition, the p-hydroxybenzoate hydroxylase which is functioned in benzoate catabolic process and protocatechuate 3,4-dioxygenase alpha subunit and protocatechuate 3,4-dioxygenase beta subunit which are functioned in 3,4-dihydroxybenzoate catabolic process were newly detected. Since these proteins are used in the degradation of benzoate, it might be speculated that the bacteria started to consume 4-HBA up to a point to be able to handle the toxic effects. It might be speculated that, the bacteria could not be able to consume all 4-HBA since phenolic acids have a dose-dependent antimicrobial property. Thus, 4-HBA resulted in serious stress conditions which led to activate this mechanism for survival. The flagellum-dependent motility proteins exopolyphosphatase, esterase EstA

and protein phosphatase CheZ exist among the new detected proteins. Flagellum is required for both virulence (Bakht azad et al., 2018) and bacterial movement in chemotaxis (Chaban et al., 2015) which aid bacteria to decide the movement according to environmental conditions. These proteins suggested that *P. aeruginosa* increases the motility and/or virulence under inconvenient environmental conditions of 4-HBA.

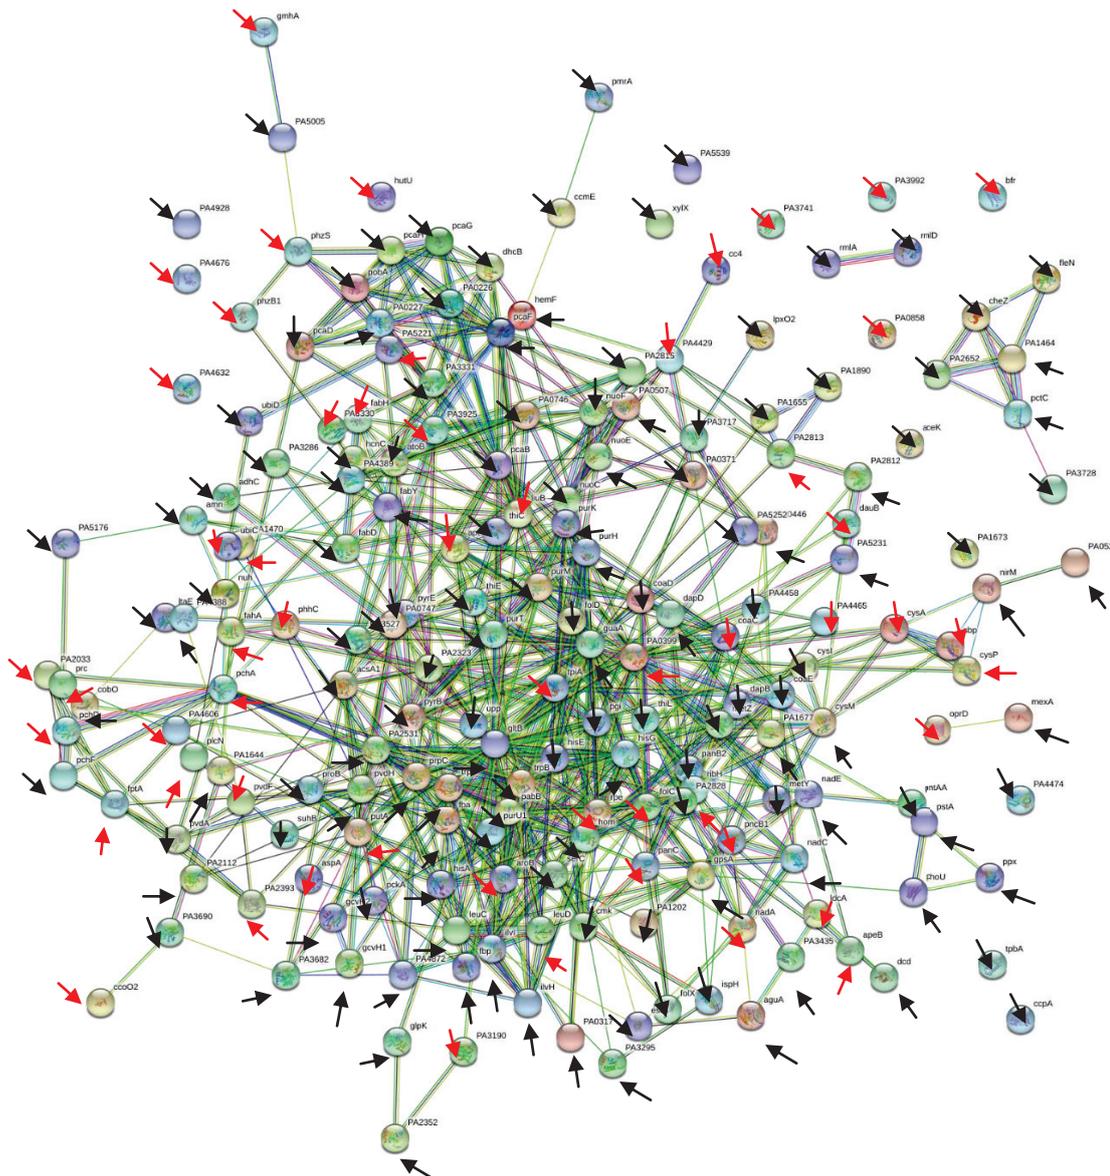

Figure 3.25. String representation of metabolism-related undetected and newly detected proteins in the presence of 4-HBA. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

Table 3.23. The undetected proteins related to metabolism in the presence of 4-HBA.

Protein ID	Protein Name	Gene Name	Function
Q9HX28	Uncharacterized protein	PA3992	Metal ion binding
Q9HYR5	Probable short chain dehydrogenase	PA3330	Dehydrogenase activity

### 3.3.2.6. Redox and Cell Homeostasis-Related Proteins of 4-HBA Treatment

The undetected (Figure 3.26 a) and newly detected proteins (Figure 3.26 b) were determined with their interaction network (Figure 3.27) related to redox and cell homeostasis in the presence of 4-HBA. According to results, various proteins functioned in oxidative stress response such as quinone oxidoreductase, superoxide dismutase [Mn] and thiol:disulfide interchange protein DsbA were undetected. On the other hand, iron-sulfur cluster assembly scaffold protein IscU functioned in iron-ion homeostasis, peptide methionine sulfoxide reductase MsrA functioned in oxidative stress response, polyamine aminopropyltransferase 1 and spermidine/putrescine import ATP-binding protein PotA functioned in spermidine biosynthesis were newly detected. In the presence of superoxide and hydrogen peroxide the DNA and membranes of the cell are seriously damaged (Hassett et al., 1996) and the bacteria require the ROS to be reduced for survival. The changes in the proteins related to response to these toxic substances demonstrated that the 4-HBA treatment resulted in the oxidative stress in *P. aeruginosa*. Relatedly, 4-HBA presented changes in the spermidine metabolism. The detection of changes in proteins of spermidine and putrescine biosynthesis, might show that the bacteria manage to handle the toxic effects of 4-HBA by these polyamines. Since they are the main polyamines in bacteria for cell viability, pathogenesis, antibiotic resistance and protecting the DNA from oxidative damage (Johnson et al., 2011) and have functions in signaling and regulation against stress conditions caused by ROS, heat, UV, acid and osmotic pressure (Bandounas et al., 2011), it could be speculated that 4-HBA showed significant stress conditions in the environment in which *P. aeruginosa* survived.

The new detection of iron-sulfur cluster assembly scaffold protein IscU which has roles in iron-ion homeostasis might demonstrate that 4-HBA caused defects in iron metabolism. Iron is the essential nutrient for cell survival regardless of being prokaryote or eukaryote (Drehe et al., 2018). It is accepted that the phenolic compounds have iron chelation properties (Singh and Kumar, 2019; Andjelkovic et al., 2006). Thus, it could be speculated that 4-HBA might chelate the iron ion in the environment which led to iron starvation of *P. aeruginosa*. Additionally, pyoverdine proteins (Pvd), which have vital roles in iron uptake (Drehe et al., 2018), were also demonstrated with a changed

protein profile in metabolism section (Table 3.23 and 3.24). Therefore, 4-HBA might show its damaging effects not only by oxidative stress but also by iron limitation for the bacteria.

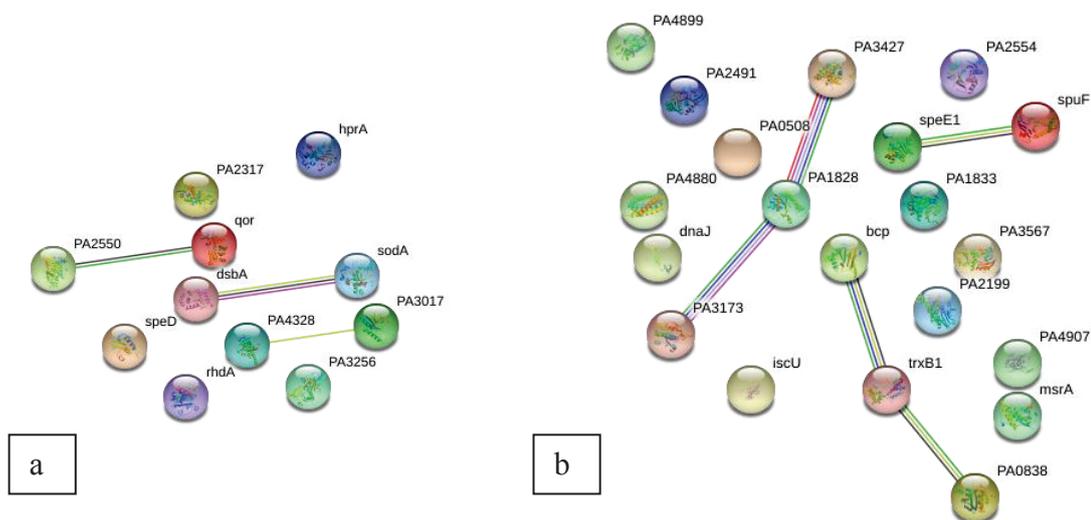

Figure 3.26. String representation of redox and cell homeostasis-related proteins in the presence of 4-HBA. a) Undetected proteins b) Newly detected proteins

### 3.3.2.7. Virulence-Related Proteins of 4-HBA Treatment

The protein 2-heptyl-4(1H)-quinolone synthase subunit PqsC (Protein ID: Q9I4X1; Gene name: pqsC PA0998) was undetected after 4-HBA treatment. This protein is a soluble signal which functioned in quorum sensing of *P. aeruginosa* leading the elevated virulence (Dulcey et al., 2013). The undetection of this protein demonstrated that 4-HBA exposure resulted in the decrease in the virulence of *P. aeruginosa* by diminishing the quorum sensing.

However, the bacteria maintained their virulence by newly detected proteins such as exoenzyme T and response regulator GacA (Table 3.27). In addition, they manage to handle the toxic effects of 4-HBA by aminoglycoside 3'-phosphotransferase type I<sub>b</sub> and regulatory protein TypA. Since these proteins have roles in the cellular response to antibiotics, it might be speculated that 4-HBA led the bacteria to protect themselves as they were exposed to antibiotics.

Table 3.27. The newly detected proteins in the presence of 4-HBA functioned in virulence.

Protein ID	Protein Name	Gene Name	Function
Q9I788	Exoenzyme T	exoT PA0044	Pathogenesis
Q9I3D8	Uncharacterized protein PA1579	PA1579	Lipid binding

Q9HU67	Regulatory protein TypA	typA PA5117	Cellular response to antibiotic, Flagellum-dependent swarming motility, cell adhesion involved in single-species biofilm formation, , positive regulation of protein secretion

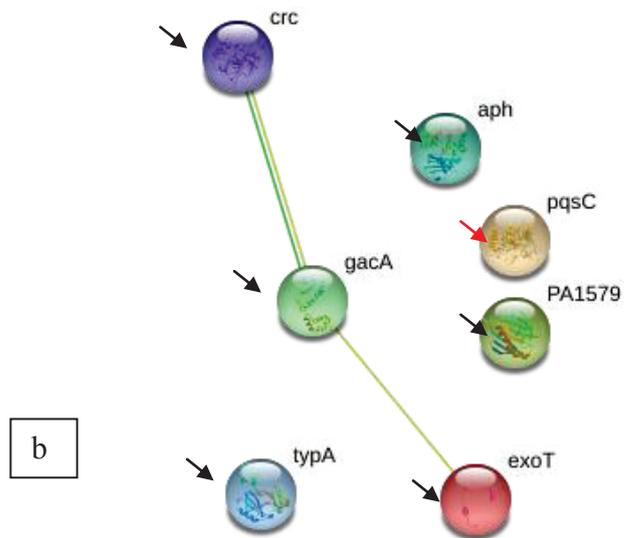

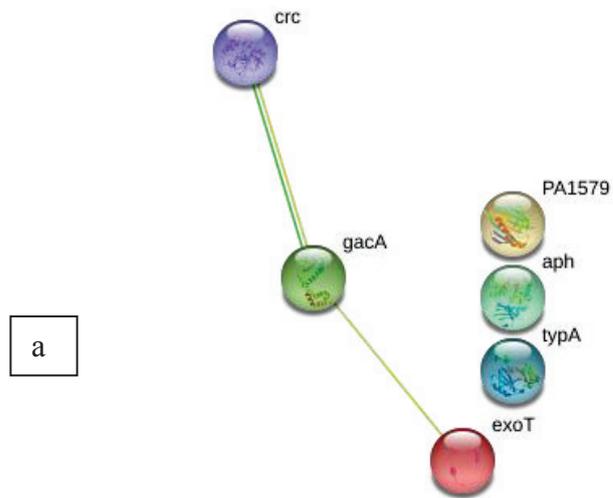

Figure 3.28. String representation of virulence-related proteins in the presence of 4-HBA. a) Newly detected proteins b) The both undetected and newly detected proteins. The proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### 3.3.2.8. Uncharacterized Proteins of 4-HBA Treatment

Various undetected (Figure 3.29 a) and newly detected (Figure 3.29 b) proteins were shown which were uncharacterized in Uniprot. The STRING results demonstrated the interaction network of these undetected and newly detected proteins (Figure 3.30).

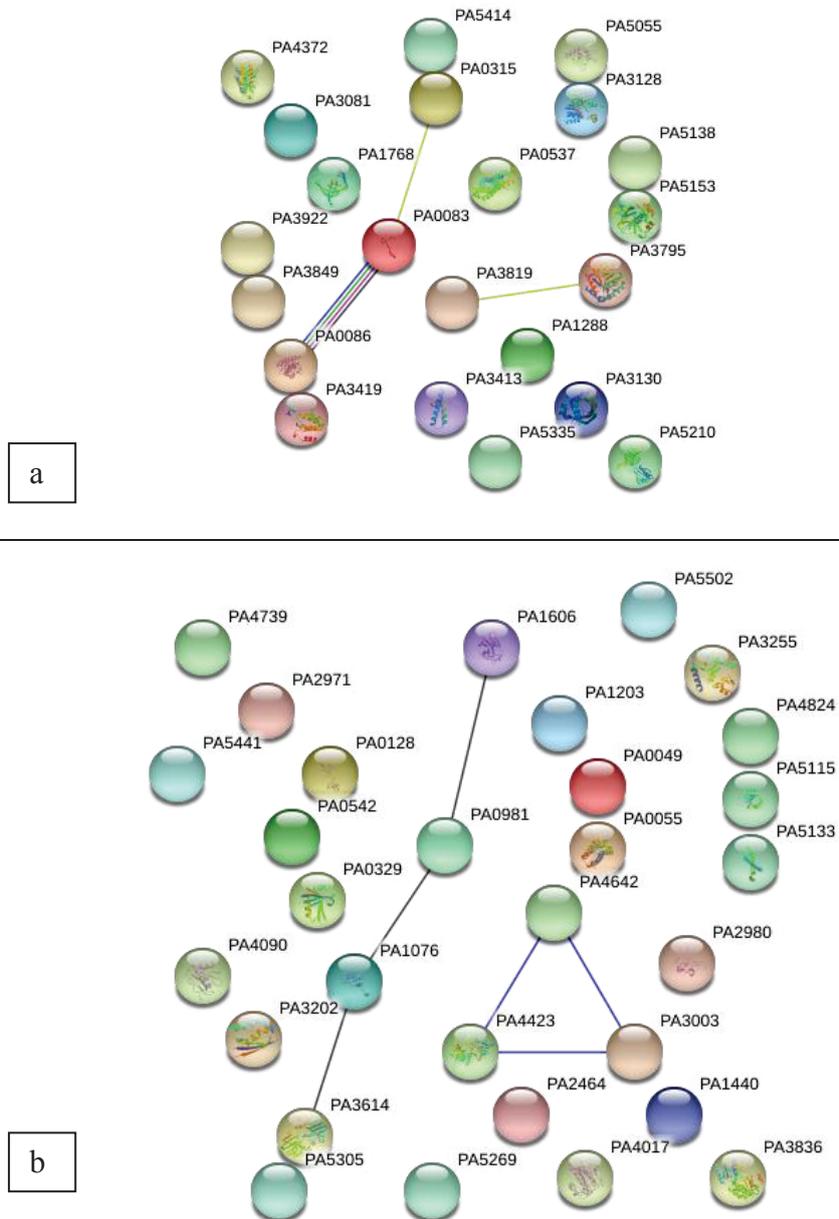

Figure 3.29. String representation of uncharacterized proteins in the presence of 4-HBA.

a) Undetected proteins b) Newly detected proteins

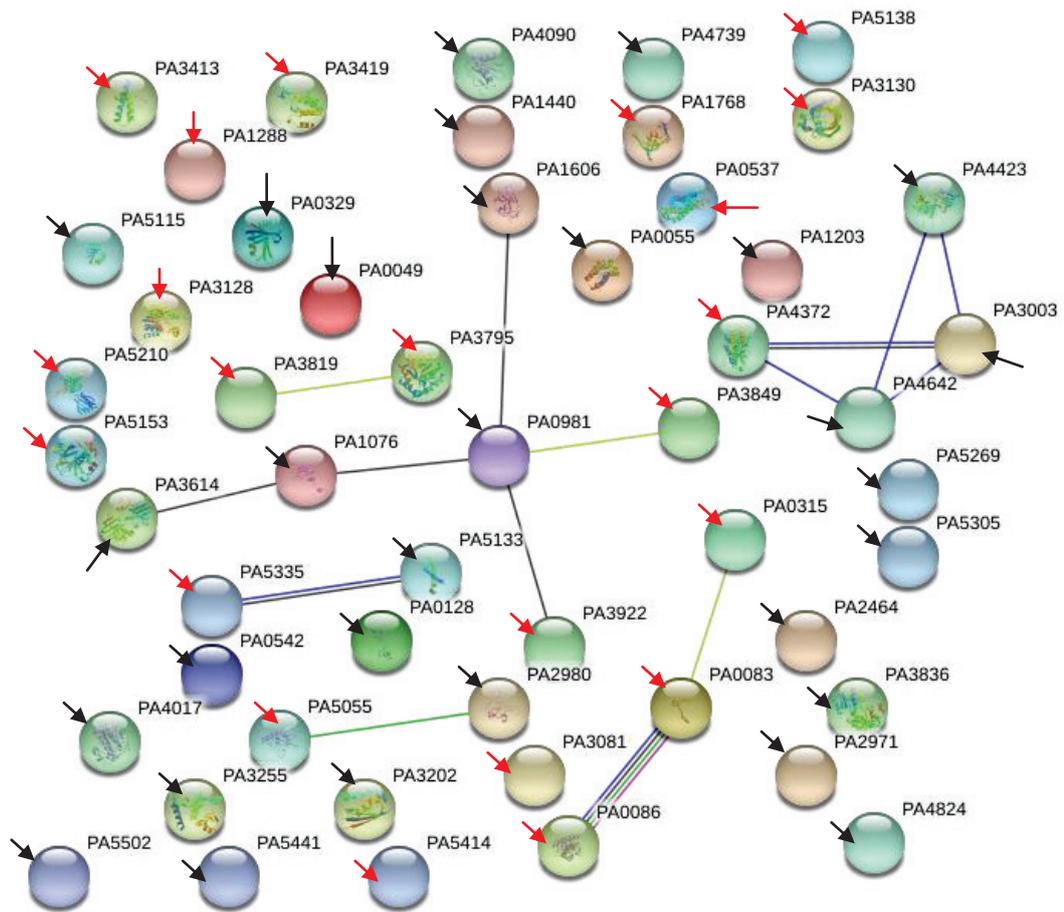

Figure 3.30. String representation of uncharacterized undetected and newly detected proteins in the presence of 4-HBA. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

The protein BLAST results showed that the uncharacterized proteins were mostly hypothetical proteins and the proteins belonging to transport systems, virulence and oxidative stress response proteins as well as structural components of various proteins (Table 3.28 and 3.29). The strongly interacted PA0086 and PA0083 were undetected after 4-HBA exposure which were functioned as tetratricopeptide repeat protein and Type VI secretion system contractile sheath small subunit, respectively (table 3.28). Type VI secretion system has a role in the competition of Gram negative bacteria with which toxic effector proteins are released into adjacent prokaryotic cell or

into eukaryotic cells by using a contractile sheath (Russel et al., 2012; Salih et al., 2018). Being virulence related, the proteins of this mechanism may be good targets of new antimicrobial agents (Salomon and Orth, 2015; Salih et al., 2018). In addition, Type VI secretion system also functions in horizontal gene transfer from lysed cells which were killed by Type VI secretion system possessing bacteria (Salomon and Orth, 2015) to obtain new genes from killed bacteria in the vicinity (Ringel et al., 2017). The undetection of these proteins might show that the treatment with 4-HBA demonstrated reduced virulence and competition properties of *P. aeruginosa*.

Another point was undetection of PA5335 which might be YicC family protein according to protein BLAST. Since it was presented as related to the DNA damage associated protein, YicC protein might be functioned in repair mechanisms. The undetection of YicC might show the DNA damage arouse from 4-HBA treatment.

Table 3.28. The undetected proteins in the presence of 4-HBA which are uncharacterized.

### 3.3.3. Comparison of Mutual Protein Profiles of 3-HPAA and 4-HBA

Although the water soluble phenolic acids 3-HPAA and 4-HBA are included in two different groups of the phenolic acids (Andjelkovic et al., 2006), the treatment of *P. aeruginosa* with each of them was resulted in various mutual proteins. This might present that the antimicrobial effects of phenolic acids are due to targeting similar biochemical pathways of *P. aeruginosa*. According to Venn diagram results which

were constructed by protein IDs of the proteins, 55 mutual proteins were newly detected for 3-HPAA and 4-HBA treatments (Figure 3.1, region II), while 108 mutual proteins were undetected (Figure 3.1, region V). Besides, 284 mutual proteins were found as mutual for control, 3-HPAA and 4-HBA treated groups (Figure 3.1, region VII). These mutual protein of phenolic acid treated groups contain proteins which were separated into groups related to their functions as DNA, RNA, ribosomes and protein, cell wall and membrane, metabolism, redox and cell homeostasis, virulence and uncharacterized. The percentages of these groups were presented in Figure 3.31 a and b for the undetected and newly detected proteins, respectively.

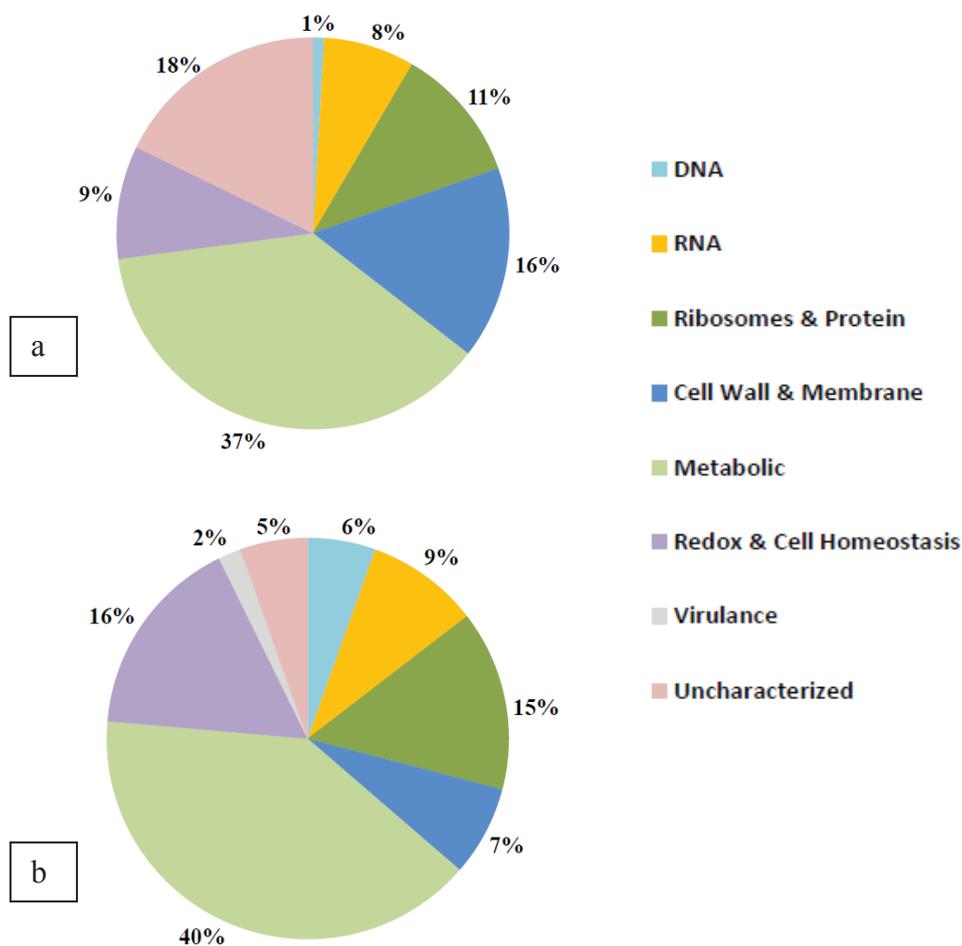

Figure 3.31. The percentages of mutual proteins for each group of function in the presence of 3-HPAA and 4-HBA. a) Undetected proteins b) Newly detected proteins

According to the results, there were no mutual virulence related proteins for each phenolic acid group which were undetected and only 2% of the newly detected mutual proteins were related to virulence. It might be speculated that the common antimicrobial effect of phenolic acids did not occur based on changes in the virulence. The changes in metabolism presented the highest percentages for both undetected and newly detected mutual proteins which indicates that the treatment with phenolic acids resulted in various metabolic changes depending on the adaptation to new environmental conditions. The most significant results were high percentage (16%) of the undetection of cell wall and membrane related mutual proteins. This might indicate that the phenolic acids mostly target cell wall and membrane proteins which led the defects in cell envelope structure and integrity. Additionally, ribosome and protein related mutual proteins showed a high undetection rate with 11% which might indicate that the other targets of the phenolic acids for antimicrobial effect are ribosome integrity and protein metabolism. On the other hand, the presence of the phenolic acids resulted in new detection of the proteins related to redox and cell homeostasis in high percentage (16%) demonstrating the high oxidative stress response of the bacteria against phenolic acid treatment.

### **3.3.3.1. DNA-Related Mutual Proteins of 3-HPAA and 4-HBA**

The treatment of *P. aeruginosa* with 3-HPAA or 4-HBA resulted in the undetection of the uncharacterized protein PA0986 which has transposase activity (Figure 3.32; Table 3.1 and 3.15). On the other hand, the recombination-associated protein RdgC, single-stranded DNA-binding protein (Ssb) and beta sliding clamp (DnaN) were newly detected, mutually (Figure 3.32). The proteins RdgC was functioned in DNA recombination as well as protein Ssb functioned in DNA recombination and repair (Table 3.2 and 3.16).

Additionally, the DnaN protein has role in DNA replication and 3'-5' exonuclease activity (Table 3.2 and 3.16). These results could be concluded as the phenolic acid treatment resulted in the damage of the bacterial genome and *P. aeruginosa* activated the DNA repair and recombination mechanisms. It is known that some bacteria including *Pseudomonas* could degrade phenolic compounds up to a point in subinhibitory concentrations (Ghaima et al., 2017). The recombination in bacteria

allow to obtain the genes with horizontal gene transfer for degradation of phenolic compounds (Tavita et al., 2012) and it aids the DNA repair systems to fix the DNA (Sidorenko et al., 2014). Therefore, *P. aeruginosa* might attempt not only to repair the defects in its genome but also attempt to protect itself by gaining new genes to adapt the new environment involving phenolic acid toxicity. Thus, one of the antimicrobial action mechanisms of phenolic acids might be due to the DNA damage of *P. aeruginosa*.

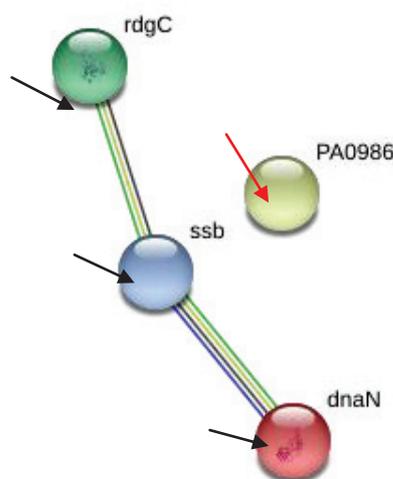

Figure 3.32. String representation of DNA-related undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### 3.3.3.2. RNA-Related Mutual Proteins of 3-HPAA and 4-HBA

The undetected and newly detected proteins functioned in transcriptional regulation of various metabolisms and RNA structure were mutual for 3-HPAA and 4-HBA displaying interactions (Figure 3.33). Bifunctional protein PyrR, DNA-binding transcriptional regulator NtrC, tRNA 2-selenouridine/geranyl-2-thiouridine synthase SelU and stringent starvation protein A (SspA) were undetected. Major cold shock

protein CspA, RNA polymerase sigma factor RpoD, phosphate regulon transcriptional regulatory protein PhoB and oxyR were newly detected after phenolic acid treatment.

Bifunctional protein PyrR is functioned in nucleoside metabolic process (Table 3.3 and 3.17) and the undetection of it might demonstrate the defects in the synthesis of nucleosides which are the subunits of nucleic acids. Thus, phenolic acids might show their effects by targetting the nucleic acid production process. DNA-binding transcriptional regulator NtrC takes role in the transcriptional regulation of nitrogen utilization (Table 3.3 and 3.17). The undetection of this protein demonstrated that the bacteria might undergo nitrogen starvation by phenolic acid treatment which led to the bacterial growth inhibition. The enzyme tRNA 2-selenouridine/geranyl-2-thiouridine synthase (protein SelU) carries out the tRNA seleno-modification (Table 3.3 and 3.17). It shows function in the formation of geranylation, a natural hydrophobic modification of tRNA, which is found in a few bacterial species involving *P. aeruginosa* (Wang et al., 2016). This modification which enhances the codon recognition fidelity and decreases the frameshift reading (Sierant et al., 2016), takes place at the wobble position of anticodons of lysine, glutamine and glutamic acid (Dumelin et al., 2012). Since the modification of tRNAs is a crucial step in tRNA biogenesis, the undetection of this protein might result in the defects in tRNA metabolism and eventually in the proper translation of proteins possessing the lysine, glutamine and glutamic acid. The sigma factors, which are important components of RNA polymerase holoenzyme, lead the adaptation and the proteins of stringent response aid the alternative sigma factors to function under stress conditions (Swiecilo and Zych-Wezyk., 2013). Therefore, the undetection of the stringent starvation protein A (SspA) might reduce the adaptation of the bacteria which might led the conclusion that the phenolic acids resulted in the defects in the stress response control of *P. aeruginosa* in their antimicrobial effect processes.

On the other hand, the newly detected major cold shock protein CspA is functioned in the repair of mRNA by stabilizing the secondary structures caused by cold stress (Bisht et al., 2014). Thus, phenolic acid treatment resulted in serious stress similar to the stress after sudden decrease of temperature and the bacteria attempt to fix the RNA function for survival by CspA protein. In addition, *P. aeruginosa* might encounter the phosphate starvation since the newly detected protein PhoB is the transcription regulator functioned in the stress response regulation under phosphate limitation (Faure

et al., 2013; Quesada et al., 2016). In the presence of phenolic acids, another vital stress response protein, OxyR was also newly detected. In addition to being one of the main transcriptional regulator of oxidative stress response (Kim et al., 2019), OxyR has also roles in iron homeostasis, quorum sensing, protein synthesis and oxidative phosphorylation (Wei et al., 2012). Therefore, when treated with phenolic acids, *P. aeruginosa* undergo serious metabolic changes to overcome the damaging effects of these stress conditions. The new detection of RpoD ( $\sigma^{70}$ ) which is the main sigma factor regulating various housekeeping genes (Potvin et al., 2008) also demonstrate the effort of the bacteria during these changes for cell survival and adaptation.

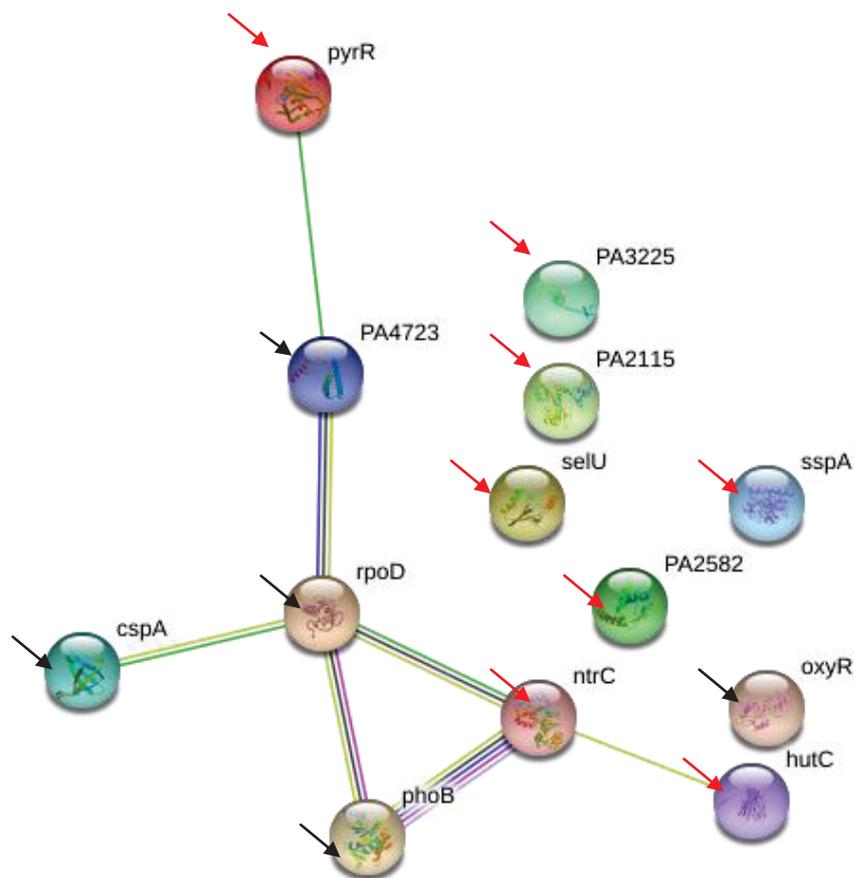

Figure 3.33. String representation of RNA-related undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### **3.3.3.3. Ribosome and Protein- Related Mutual Proteins of 3-HPAA and 4-HBA**

The treatment with phenolic acids resulted in the problems in ribosome structure and assembly. For instance, small ribosomal subunit biogenesis GTPase RsgA and 30S ribosomal protein S15 rpsO were undetected. The protein S15 is one of the main ribosomal proteins functioned in the assembly of the ribosomal small subunit (Shajani et al., 2011; Liu and Fredrick, 2016) and RsgA is an important enzyme functioned in the small subunit assembly. In addition, ATP-dependent RNA helicase DeaD and ribosomal RNA large subunit methyltransferase J (rimJ) which are functioned in ribosomal large subunit assembly were also undetected. These might indicate that phenolic acids block the proper ribosomal structure and assembly process. Since the large subunit is the major part of the ribosome for the polypeptide translation (Aseev and Boni, 2011), undetection of these proteins eventually affected the protein translation by damaging the ribosome structure and assembly. Since 30S ribosomal protein S18 (rpsR) was newly detected, it might show that the bacteria managed to continue the maintained ribosomal small subunit assembly. Translational initiation was also damaged by phenolic acids since Translation initiation factor IF-1(infA) functioned in ribosome binding, rRNA binding and translation initiation was undetected. Besides the effects on ribosome and translation, protein metabolism was defected by undetection of Protein-export protein SecB. This protein is a molecular chaperone which recognizes the N-terminal signal sequence of some precursor proteins and functions in the translocation of them for proper protein production. Since SecB was undetected, it might be concluded that serious changes occurred in the protein metabolism including the defects in the process of the proteins with N-terminal signal sequences (Driessen, 2001).

D-ala-D-ala-carboxypeptidase (DacC) was newly detected which is functioned in the synthesis of peptidoglycan layer, the main component of the bacterial cell wall wall (Ghosh et al., 2008; Meyer et al., 2018). The bacteria use this enzyme in the recycling of the peptidoglycan layer subunits which were released into media (Templin et al., 1999; Meyer et al., 2018). This could demonstrate that the bacterial cell wall was damaged and *P. aeruginosa* attempted to fix it by using carboxypeptidase. The t-RNA ligases such as IleS, TyrS2, GltX and MetG were newly detected after phenolic acid exposure which presented that the phenolic acids resulted in an increase for some

tRNAs for the metabolism changes for adaptation. Since t-RNAs are the main components for aminoacids transfer to the ribosomes to maintain the growth of peptide chain in translation (Ferro et al., 2018), it could be concluded that the phenolic acids affected the protein synthesis profile of *P. aeruginosa*.

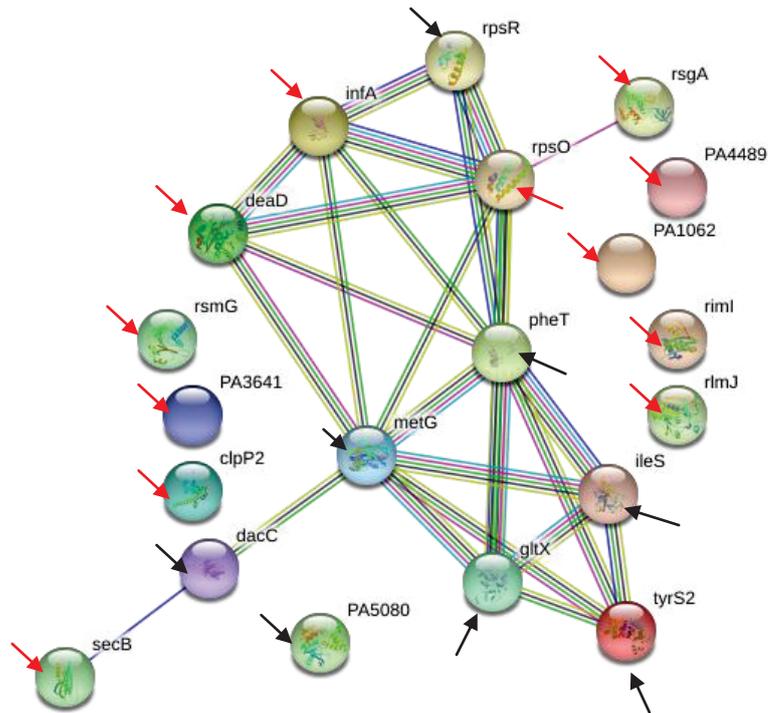

Figure 3.34. String representation of ribosome and protein-related undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### 3.3.3.4. Cell Wall and Membrane- Related Mutual Proteins of 3-HPAA and 4-HBA

The undetected proteins share many mutual proteins in the treatments with 3-HPAA and 4-HBA (Table 3.7 and 3.21). Therefore, the effect of 4-HBA and 3-HPAA

might be carried out by damaging similar cell wall structures. YidC is one of the important proteins for the insertion and integration of small membrane proteins into the membrane (Dalbey et al., 2011; Kiefer and Kuhn, 2018). The protein FtsY has a role in the targetting of nascent polypeptide chains to the membrane for the transfer of them to the cytoplasmic region of the membrane (Dalbey et al., 2011). Hence, the undetection of YidC and FtsY demonstrated the phenolic acids blocked the targetting and insertion of new proteins into the membrane which might lead the antimicrobial effect due to defects in the cell wall structure. Additionally, another vital protein for cell wall integrity and cell metabolism, FtsH, was undetected. This protein is conserved among prokaryotes and functioned in the regulation control of the cell metabolism in the case of an environmental stress (Langklotz et al., 2012). It is a protease attached to the inner membrane (Narberhaus et al., 2009) and has roles in quality control of the membrane proteins (Langklotz et al., 2012) as well as posttranslational modifications of transcription factors and enzymes (Narberhaus et al., 2009). The undetection of this protein might point out another target for the phenolic acids for their antimicrobial effects

Another meaningful result of the antimicrobial effects of phenolic acids might be presented with the undetection of the proteins related to flagellum and type IV pili. The bacteria can sense the environmental changes and use chemotaxis for either going towards desirable or escape from the undesirable environments. Since the motility for chemotaxis might be carried out by flagellum, the changes in their proteins might be considered as a bacterial attempt to adapt the new conditions. For instance, B-type flagellin (FliC) which has a role in the flagellum organization and motility (Bakht azad et al., 2018) was newly detected while CheY protein functioned in rotation of the flagellum (Chaban et al., 2015) was undetected. These situations might show both the adaptation and the damage in the chemotaxis process. The flagellum has important roles in the virulence and the movement for chemotaxis (Bakht azad et al., 2018; Chaban et al., 2015). Therefore it could be speculated that the B-type flagellin (FliC) was produced for the flagellum synthesis for increased motility or virulence due to phenolic acids. However, since the CheY protein was undetected, the movement with flagellum was defected. This might present that phenolic acids resulted in the damage in the chemotaxis and diminished the swimming motility with the flagellum which could cause the antimicrobial effect. The proteins related to another mechanism, the type4 pili,

was also undetected. The type4 pili are the filaments found in the poles of *P. aeruginosa* which are flexible (Kazmierczak et al., 2006). These structures are serious virulence factors that aid the initiation of the infections (Huang et al., 2003) as well as the biofilm formation (Jain et al., 2017). The type4 pili is functioned in the twitching motility which is a flagellum-independent motility of the bacteria (Huang et al., 2003; Carter et al., 2017). The protein PilY1 is one of the proteins of type4a pilus (Carter et al., 2017) which is the type4 pili found in *P. aeruginosa* (Giltner et al., 2012). The undetection of PilY1 protein may suggest that the phenolic acids caused defects in the twitching motility and biofilm formation of *P. aeruginosa*. Thus, the motility of the bacteria was seriously affected by the phenolic acid treatments.

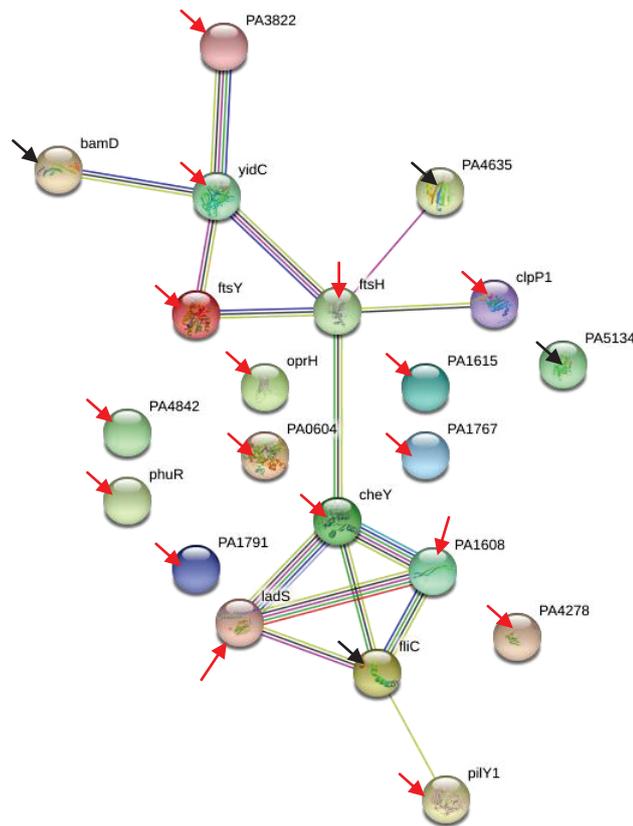

Figure 3.35. String representation of cell wall and membrane-related undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

The outer membrane protein assembly factor BamD and probable carboxyl-terminal protease PA5134 which have roles in the cell envelope biogenesis (Mori et al., 2012) were newly detected after phenolic acid treatments. It demonstrated that the phenolic acids might damage the cell envelope, especially the outer membrane of *P. aeruginosa* which was attempted to be fixed by BamD and carboxyl-terminal protease for maintained cell wall integrity.

### **3.3.3.5. Metabolism- Related Mutual Proteins of 3-HPAA and 4-HBA**

Many mutual proteins related to various metabolic processes were presented after phenolic acid exposures. The changes in the protein profiles of the bacteria related to energy metabolism (i.e. undetection of Rpe functioned in carbohydrate metabolic process), amino acid metabolism (i.e. undetection of Apt functioned in purine ribonucleoside salvage and new detection of GuaA functioned in GMP biosynthesis in purine metabolism) and lipid metabolism (i.e. new detection of AtoB functioned in fatty acid beta oxidation) (Table 3.23 and 3.24) showed that the bacteria undergo many metabolic changes to adapt the environment containing phenolic acids for a maintained metabolism. Besides these expected changes originated from the adaptation processes, some changes were also demonstrated which might aid the antimicrobial effect of the phenolic acids. The sulfate transport of *P. aeruginosa* was diminished since sulfate/thiosulfate import ATP-binding protein CysA, sulfate-binding protein of ABC transporter (CysP) and sulfate-binding protein (Sbp) were undetected. Therefore phenolic acids resulted in the sulfate limitation which might led the growth inhibition of the bacteria. The iron starvation might be another result of the presence of phenolic acids since the protein Fe(3+)-pyochelin receptor (FptA) was mutual in the undetected proteins related to iron homeostasis. Since the phenolic compounds are metal chelators (Singh and Kumar, 2019; Andjelkovic et al., 2006), the environment containing phenolic acids might result in the non-utilizable iron which caused the inhibition of the bacterial growth under iron limitation stress. Besides these, the phenolic acids showed reduced virulence with the undetection of proteins related to phenazine production of *P. aeruginosa*. Since phenazine biosynthesis protein PhzB1 and 5-methylphenazine-1-carboxylate 1-monooxygenase proteins were undetected, phenolic acids damaged the in phenazine biosynthetic process, reducing the virulence.

### 3.3.3.6. Redox and Cell Homeostasis- Related Mutual Proteins of 3-HPAA and 4-HBA

The phenolic acid treatment resulted in the mutual changes in the protein profile related to redox and cell homeostasis which indicates that both phenolic acids caused oxidative stress on *P. aeruginosa*. Additionally, the undetection of the proteins functioned in oxidative stress response might show that the phenolic acids led the reducing of the redox homeostasis for the antimicrobial effect. For instance, Superoxide dismutase [Mn] (SodA) and thiol:disulfide interchange protein DsbA were undetected. Superoxide dismutase [Mn] is functioned in removal of superoxide radicals (Table 3.11 and 3.25) (Iiyama et al., 2007) while DsbA in cell redox homeostasis. The protein thiosulfate sulfurtransferase (RhdA) which takes role in response to toxic substance and aids to survival of *P. aeruginosa* under stress conditions was also undetected. Since the redox homeostasis and removal of superoxides are required to protect the DNA from the damage in the DNA and membranes (Hasset et al., 1996), the undetection of these proteins showed the enhanced oxidative stress due to diminished oxidative stress response. On the other hand, S-adenosylmethionine decarboxylase proenzyme speD was undetected whereas SpeE1 and SpuF were newly detected. These proteins are functioned in the spermidine biosynthesis and transport processes. Spermidine is a polyamine which functions in the cell viability, pathogenesis, antibiotic resistance and signaling and regulation against stress conditions caused by reactive oxygen species (ROS), heat, UV, acid and osmotic pressure (Johnson et al., 2011; Bandounas et al., 2011). The undetection of SpeD might be compensated by the new detection of SpeE1 and SpuF to continue the spermidine biosynthesis. Other newly detected proteins, Chaperone protein DnaJ and Glutathione peroxidase PA0838 are functioned in the response to hyperosmotic and heat shock and Response to oxidative stress, respectively. One of the main enzymes which takes role in the stress caused by chemicals such as phenolic compounds (Tamburro et al., 2001), Peptide methionine sulfoxide reductase MsrA was also newly detected. This protein is vital for the repairing the proteins which become unfunctional by oxidative stress damage (Mintz et al., 2002, John et al., 2001). Thus, it is clear that phenolic acids degrade the cell homeostasis of *P. aeruginosa* by causing serious oxidative stress.

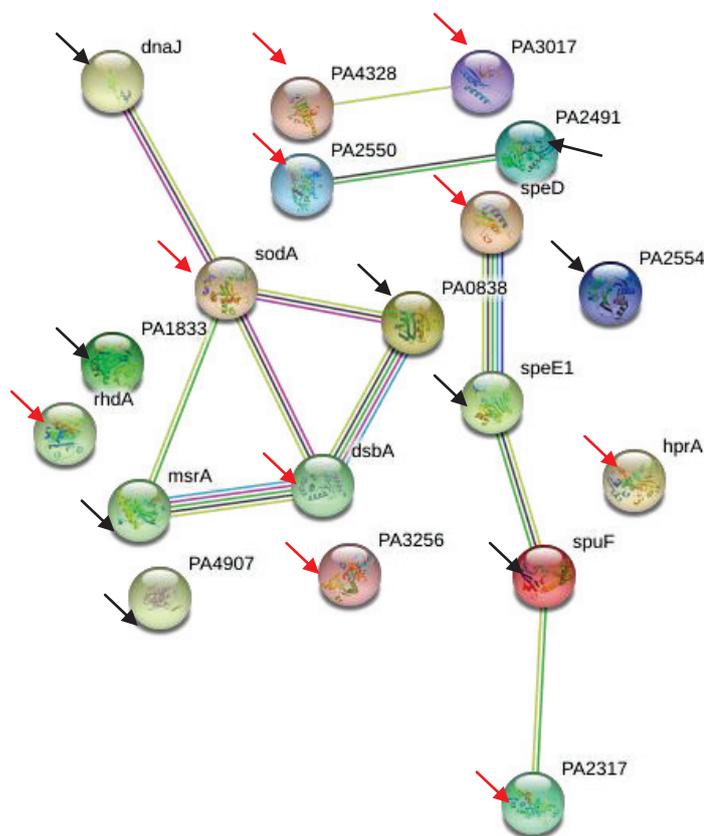

Figure 3.37. String representation of redox and cell homeostasis-related undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

### 3.3.3.7. Virulence- Related Mutual Proteins of 3-HPAA and 4-HBA

The Uncharacterized protein PA1579 (Protein ID: Q9I3D8; Gene Name: PA1579) functioned in lipid binding (Table 3.27) was the only mutual newly detected protein for 3-HPAA and 4-HBA and no undetected proteins exist related to virulence. It might be concluded that, although the phenolic acids resulted in the changes in the virulence of *P. aeruginosa* individually, their effects related to virulence was not via the same protein profile.

### 3.3.3.8. Uncharacterized Mutual Proteins of 3-HPAA and 4-HBA

The most notable change in the uncharacterized protein profile were the undetection of PA0086 and PA0083 which showed strong interactions. These proteins were suggested as Tetratricopeptide repeat protein (PA0086) and Type VI secretion system contractile sheath small subunit (PA0083) in the protein BLAST.

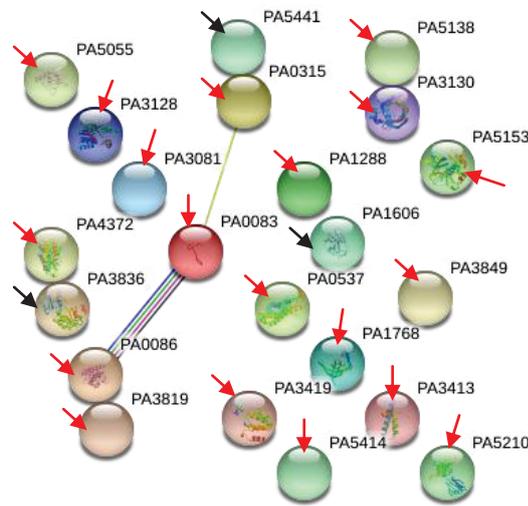

Figure 3.38. String representation of uncharacterized, undetected and newly detected mutual proteins in the presence of phenolic acids. The significant proteins were indicated in arrows with different colors (Undetected proteins: red arrows and newly detected proteins: black arrows).

Type VI secretion system (T6SS) is an important mechanism of Gram negative bacteria to compete to each other and functions to secrete effector proteins in adjacent bacteria by its contractile sheath part (Russel et al., 2012; Salih et al., 2018). The most notable function of this system is its role in horizontal gene transfer. The bacteria use this mechanism to lyse the other bacteria in the vicinity with T6SS system to gain the new genes (Salomon and Orth, 2015). It is also a virulence factor and it is accepted as a good target for new antimicrobials (Salomon and Orth, 2015; Salih et al., 2018). The

undetection of small subunit of contractile sheath resulted in the defect of this system of *P. aeruginosa*. Relatedly, tetratricopeptide repeat protein which is functioned in the exporting the secretions from cell membrane (Whitney and Howell, 2013; Mejias et al., 2019) was also undetected. Therefore, the phenolic acids might target T6SS mechanism of *P. aeruginosa* for their antimicrobial effects which led the decreasing in virulence, competing property and horizontal gene transfer.

To conclude; tested water soluble, simple phenolic acids, 3-HPAA and 4-HBA could be presented as “multi-target antimicrobial agents” since they resulted in the changes in various metabolic processes of *P. aeruginosa*, such as DNA, RNA, ribosomes, proteins and cell envelope as well as cell homeostasis and virulence at the proteomic level. The most notable targets for tested phenolic acids could be presented as their effects on the cell wall and membrane integrity as well as their damages from serious oxidative stress. Other vital systems, ribosome structure, assembly and protein metabolism were also highly affected in the presence of phenolic acids. It is known that many antibiotics show their antimicrobial effects on one system of the bacteria which might lead to the immediate drug resistance development of bacteria. Thus, phenolic acids could be more useful antimicrobial agents since they have more than one targets in bacterial metabolism and there are any known resistance mechanism of the bacteria against them. They showed not only the bacteriocidal effects on *P. aeruginosa* but also diminished probability of resistance by targetting many metabolic pathways. Thus, the phenolic acids could be considered as promising antimicrobial agents against serious pathogenic bacteria.

#### **3.3.4. Validation of Protein Data by RT-qPCR**

The protein data was validated at the transcription level by real time quantitative polymerase chain reaction (RT-qPCR). Since protein data was obtained from the 18 hours cultures which was the very beginning of the stationary phase, total RNA samples were isolated from the 18 hour cultures of *P. aeruginosa*. Since the ribosomal rpsL gene, which encodes the S12 protein of 16S rRNA, was shown in the mutual proteins for control, 3-HPAA or 4-HBA treated bacteria and it was presented as the housekeeping (reference) gene for *P. aeruginosa* in RT-qPCR in the literature (Dumas et al., 2006; Llanes et al., 2004), it was chosen as reference gene in RT-qPCR. In the

protein data, S15 protein of 16S rRNA was undetected in the presence of each phenolic acid. S15 protein is one of the important constituents of small subunit of prokaryotic ribosome (Aseev and Boni, 2011). It was demonstrated that it is required for ribosome assembly and it provides an important bridge between small and large subunits *in vitro* (Serganov et al., 2003; Geissmann et al., 2009) and it was required for the proper ribosome assembly in the stress conditions *in vivo* (Bubunenکو et al., 2006). Hence, the rpsO gene which encodes the S15 ribosomal protein, was determined to be validated by RT-qPCR to show the decreased expression of it. The primers specific to these genes were designed for these genes by Primer BLAST database were shown in Table 3.30.

Table 3.30. The primers used in RT-qPCR.

Genes	F Primer	R Primer
rpsL	CGTACATCGGTGGTGAAGGT	CGACCCTGCTTACGGTCTTT
rpsO	TACAAGCAAGCTGAAGGCGA	CCATACGGATCAGACCACGG

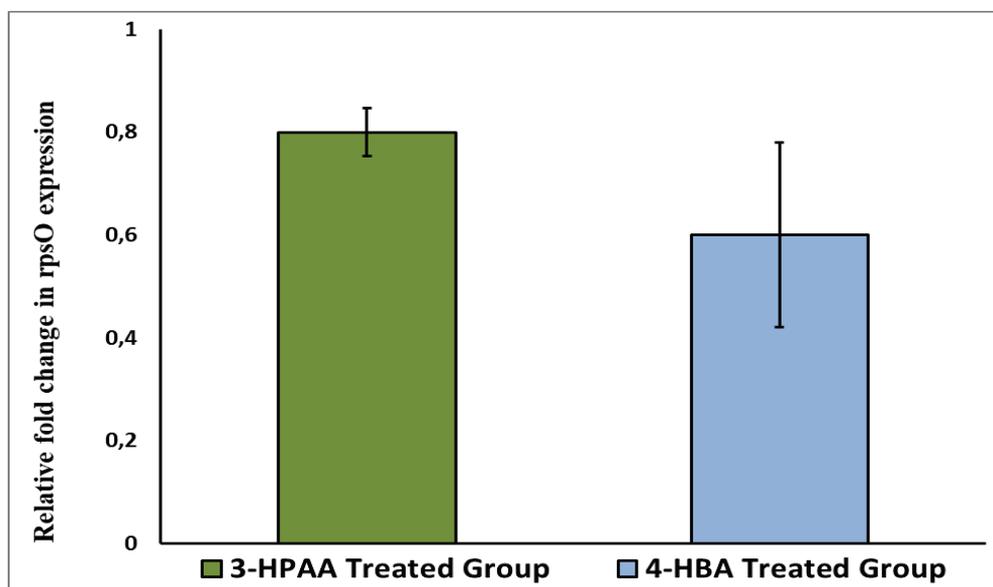

Figure 3.39. Relative fold change in the expression of rpsO gene. Average fold change of control group is 1.0. Normalization was performed based on rpsL gene expression and untreated group.

According to the calculations based on delta Ct method, the results of three biological samples and three technical repeats were found. The average fold change in Ct values of mRNA expression of rpsO gene was 0.8 ( $\pm 0.04$ ) for 3-HPAA treated cells while it was 0.6 ( $\pm 0.2$ ) for 4-HBA treated cells. The normalization was performed for the mRNA expression of housekeeping gene and untreated group (as 1.0 in fold change). These results showed that 3-HPAA treatment resulted in a 1.3 fold decrease and 4-HBA treatment resulted in a 1.7 fold decrease in the expression of rpsO gene which is consistent with the protein data (Figure 3.39).

## CHAPTER 4

# THE ANTIMICROBIAL EFFECTS OF PHENOLIC ACID LOADED ALGINATE-CHITOSAN NANOPARTICLES ON PATHOGENIC BACTERIA

### 4.1. Introduction

Pathogenic bacteria are serious treats for human health since they result in serious infections in humans, worldwide. Nosocomial pathogens (i.e. *Pseudomonas aeruginosa*, *Staphylococcus epidermidis*, methicillin resistant *Staphylococcus aureus*, methicillin susceptible *Staphylococcus aureus*, *Acinetobacter haemolyticus*) and food-borne pathogens (i.e. *Escherichia coli* O157H:7, *Salmonella* Enteritidis and *Listeria monocytogenes*) are well-known pathogenic bacteria which cause high morbidity and mortality. The treatments of the infections caused by these bacteria are carried out by antibiotics in use. However, these bacteria have resistance against many of the antibiotics as well as they can develop resistance during the treatment. Thus, it is a challenge to combat these bacteria. Therefore, bioactive compounds are in search as new antimicrobial agents all over the world.

The phenolic acids, which are synthesized as secondary metabolites by almost all plants (Hurtado-Fernandez et al., 2010), are accepted as promising candidates of new antimicrobial agents. Their structures consist of the benzene ring with one or more hydroxyl groups and sometimes additional radical groups (Hurtado-Fernandez et al., 2010). The phenolic acids and the plant extracts that contain phenolic compounds were shown in many studies for their antimicrobial properties (Karaosmanoglu et al., 2010; Gutiérrez-Larraínzar et al., 2012; Díaz-Gómez et al., 2013; Cueva et al., 2010; Albanoa et al., 2019). However, they are sensitive to environmental conditions which may result in decreasing or fluctuating antimicrobial effects. Encapsulation of bioactive compounds, which catches attention in the studies of biomedical field, may facilitate the long term stability and preserved therapeutic effects (Krausz et al., 2015). Structural durability of phenolic acids by encapsulation are achieved by decreasing the oxidation

and/or degradation of them (Li et al., 2015). Nowadays, there are many studies which show the antimicrobial effects of encapsulated antimicrobial agents in an increasing manner (Khan et al., 2019; MubarakAli et al., 2018; Liu et al., 2018; Wu et al., 2018; Ananda et al., 2019; Wintachai et al., 2019). The results of these studies indicate efficient results to combat pathogenic bacteria with encapsulated agents.

The phenolic acids used in this study, 3-hydroxyphenylacetic acid (3-HPAA) and 4-hydroxybenzoic acid, are water-soluble, simple phenolic acids with dose-dependent antimicrobial activities which were determined in our previous studies (chapter 2). In the current study, it was aimed to show the antimicrobial effects of encapsulated 3-HPAA and 4-HBA in the solution form on nosocomial and food-borne pathogens.

The encapsulation of bioactive compounds could be achieved by using polymers such as chitosan and alginate. Since these materials are both biocompatible and biodegradable with easy-to-use natures, they are frequently used for this purpose (Paques et al., 2014). Cationic polymer, chitosan, is obtained from chitin and it has antimicrobial properties (Jayakumar et al., 2010). It can be used to make effective substances by combining with vitamins, minerals, oils, proteins and biologically active natural compounds (Tang et al., 2013; Azevedo et al., 2014; Budnyak et al., 2016; Deka et al., 2016; Wu et al., 2018; Moschona and Liakopoulou-Kyriakides, 2018). Alginate, which is also a polymer, is obtained from algae. It is water soluble and has anionic nature (Paques et al., 2014). Since it can be used to synthesize hydrogels in the presence of divalent cations, it is an important encapsulation material (Yang et al., 2011).

In our study, encapsulations of 3-HPAA and 4-HBA into alginate- chitosan nanoparticles were achieved via ion gelation technique. In the first step, the complexes of alginate with 3-HPAA or 4-HBA were produced by calcium chloride ( $\text{CaCl}_2$ ) which was used as a cross-linker. Then these pre-gels were covered with chitosan as the outermost layer of the nanoparticles. Coating of the anionic polymer, alginate, with a cationic polymer, chitosan, produces the alginate-chitosan nanoparticles by electrostatic interactions (Liu et al., 2018) with enduring coat and high structural stability (Paques et al., 2014).

Herein we report the synthesis, physico-chemical characterization and *in vitro* antimicrobial effects of alginate-chitosan nanoparticles on various pathogenic bacteria. The alginate chitosan nanoparticles loaded with 3-HPAA (3-HPAA-Alg-Chi) or 4-HBA

(4-HBA-Alg-Chi) were investigated in comparison to their unloaded alginate-chitosan nanoparticles (null nanoparticles).

## **4.2. Materials and Methods**

All of the materials; low molecular weight chitosan, low viscosity alginic acid sodium salt, calcium chloride dihydrate, sodium hydroxide, hydrochloric acid, acetic acid, 3-hydroxyphenylacetic acid, 4-hydroxybenzoic acid, ethanol, agar were purchased from Sigma-Aldrich while tryptic soy broth was purchased from Merck. Ion gelation technique was used in the production of nanoparticles. Null nanoparticles (without any antimicrobial agents) and phenolic acid loaded nanoparticles (3-HPAA-Alg-Chi and 4-HBA-Alg-Chi) were produced under aseptic conditions with sterile equipments and solutions.

### **4.2.1. Preparation of Alginate-Chitosan Nanoparticles**

Alginate-Chitosan nanoparticles were prepared based on the protocol of Azevedo et al. with the modification of increasing in the concentration of  $\text{CaCl}_2$  (Azevedo et al., 2014).

The alginate solution was prepared by dissolving sodium alginate (0.63 mg/ml) in double distilled water ( $\text{ddH}_2\text{O}$ ). The pH of the alginate solution was adjusted to pH 4.9 by 1 M hydrochloric acid (HCl). This solution was used in null nanoparticle production. Besides that, in phenolic acid loaded nanoparticle productions, the alginate solutions with additions of 3-HPAA (3mg/ml or 25 mg/ml) or 4-HBA (2.8 mg/ml) were used. Chitosan solution was prepared by dissolving the chitosan (low molecular weight) (0.4 mg/ml) in sterile 1% acetic acid (in  $\text{ddH}_2\text{O}$ , v/v). The pH of chitosan solution was adjusted to pH 4.6 by 1 M sodium hydroxide (NaOH).

The stock solution of calcium chloride ( $\text{CaCl}_2$ ) in 25 mM was prepared by dissolving calcium chloride dihydrate in  $\text{ddH}_2\text{O}$  and autoclaving before usage. This solution was used as cross-linker by addition in 7.5 ml into alginate solution on ice with 0.125 ml/min flow rate for each type of nanoparticle. During this step, Ultra-Turrax was used to have continuous 20.000 rpm stirring for homogenization. Prepared chitosan solution was added onto alginate- $\text{CaCl}_2$  pre-gel (for null nanoparticles) and onto

alginate-phenolic acid-CaCl<sub>2</sub> pre-gel (for phenolic acid loaded nanoparticles) with 0.278 ml/min flow rate for each with 600 rpm continuous stirring. Alginate and chitosan were used in the 5:1 volume ratio (alginate:chitosan) for each nanoparticle solution. Prepared nanoparticle solutions were allowed to stir 20 more minutes and they were kept at 4°C until usage.

In each study, required volumes of the nanoparticle solutions were vortexed for 30 seconds and sonicated for 30 minutes at 4°C before usage. Sonication bath was kept cold by using ice cubes during sonication.

#### **4.2.2. Characterization of Nanoparticles**

The prepared nanoparticles were investigated via Dynamic Light Scattering (DLS), Fourier Transform Infrared Spectrometry (FT-IR) and Scanning Electron Microscopy (SEM).

##### **4.2.2.1. Dynamic Light Scattering (DLS)**

The determination of size distributions (by number distribution) and polydispersity indexes (PDI) of nanoparticles were performed by dynamic light scattering (DLS) by Zetasizer (Nanoplus 3 Zeta/nano particle analyzer, Micromeritics) with Nanoplus version 5.22/3 software. Analyses were performed at a scattering angle of 165°, refractive index of 1.3, repetition of 2 and temperature of 25°C.

Each sample in 3 ml volume was investigated in disposable DLS cuvettes immediately after sonication. Average and standard deviation calculations were done by Microsoft Excel software.

##### **4.2.2.2. Fourier Transform Infrared Spectrometry (FT-IR)**

The infrared spectra measurements were performed by FT-IR spectrometer (PerkinElmer Spectrum 2) equipped with a deuterated tri-glycine sulphate (DTGS) detector and a horizontal attenuated total reflectance (HATR) sampling accessory (ZnSe crystal). The spectra were recorded in the mid-infrared (4000-650 cm<sup>-1</sup> wavenumber)

range by transmittance (T%) values at room temperature with the number of scans of 20 and resolution of 4 cm<sup>-1</sup>. Each nanoparticle solution was lyophilized for 24 hours (Labconco-Freezone) before FT-IR measurements. After collecting the background spectra prior to measurements, the nanoparticles (null, 3-HPAA-Alg-Chi and 4-HBA-Al-Chi), chitosan, alginate, 3-HPAA and 4-HBA were placed on the crystal region of the instrument individually and compressed by metal arm until a stable force gauge value was achieved. The data were collected by Spectrum software (Version 10.4.3). In between each measurement ZnSe crystal was cleaned by isopropyl alcohol.

#### **4.2.2.3. Scanning Electron Microscopy (SEM)**

Sonicated samples were centrifuged at 18,000 x g at 4°C for 30 minutes. They were diluted by dissolving the pellet in ddH<sub>2</sub>O with 2-fold of the original solution volume. Diluted nanoparticle solutions were vortexed and sonicated for 5 minutes. Then, 10 µl of the samples were placed on aluminum foil and allowed to dry at 37°C for 30 minutes. These samples were placed on double-sided carbon bands on metal grids. They were covered by gold for 2 minutes and investigated under SEM (Philips XL 30). Micrographs of the nanoparticles were taken with different magnifications.

#### **4.2.3. Encapsulation Percentages of Phenolic Acids**

The encapsulation percentages of phenolic acids into Alg-Chi nanoparticles were determined by UV-visible spectrophotometer (Thermo Multiscan) measurements.

##### **4.2.3.1. UV-Visible Peaks of Phenolic Acids**

Stock solutions of 3-HPAA and 4-HBA were dissolved in ddH<sub>2</sub>O (1 mg/ml) individually. To see the peak of the solution clearly, the dilutions of 10-fold, 50-fold, 100-fold and 500-fold of each stock solution were prepared in ddH<sub>2</sub>O and were subjected to UV-Spectrum scanning. The measurements were performed in the range of 200-400 nm wavelength by using quartz cuvettes in 1ml volume. The wavelengths that show significant peaks were chosen for each phenolic acids for further studies.

#### 4.2.3.2. Standard Graphs of Phenolic Acids

The stock solutions of 3-HPAA and 4-HBA were prepared (1 mg/ml) in ddH<sub>2</sub>O. The dilutions in 0.001 mg/ml, 0.002 mg/ml, 0.005 mg/ml, 0.01 mg/ml and 0.02 mg/ml concentrations were prepared and measured spectrophotometrically in UV-Vis spectrum by using quartz cuvettes (1 ml). The wavelengths which were pre-determined in UV-Spectrum scanning analyses were used for each phenolic acid. The standart curves were plotted by absorbance values (nm) of each dilution versus concentration (mg/ml) of the dilutions (Microsoft Excel). Slope equations and R<sup>2</sup> values were indicated to use in calculations in further steps.

#### 4.2.3.3. Calculation of Encapsulation Percentages

The encapsulation percentages of phenolic acids into Alg-Chi nanoparticles were calculated by using the concentrations of the phenolic acids in the supernatant of nanoparticles. For this purpose, phenolic acid loaded nanoparticle solutions were vortexed for 30 seconds and sonicated for 30 minutes. The solutions were centrifuged at 18000 x g for 30 minutes. The supernatants were measured spectrophotometrically by using quartz cuvettes in 1 ml volume at pre-determined wavelengths. According to equations of the standard curves of each phenolic acid, the concentrations of phenolic acids were calculated in mg/ml by using the absorbance values. These concentration values were called “supernatant phenolic acid concentration” in the calculation of percentages (equation 4.1). The encapsulation percentage for each phenolic acid was calculated according to the equation 4.1 below. In the equation, “total phenolic acid concentration” indicates the total phenolic acid amount that was used in nanoparticle preparation. The measurements and the calculations were performed in duplicates.

$$\text{(Encapsulation \%)} = 100 - \left( \frac{\text{Supernatant phenolic acid conc.}}{\text{Total phenolic acid conc.}} \right) \times 100 \quad (4.1)$$

#### 4.2.4. Antimicrobial Effects of Nanoparticles

During all antimicrobial experiments; bacteria were maintained on tryptic soy agar (TSA) plates by inoculation of a single colony on fresh agar plate every week. The bacteria were grown overnight at 37°C. The bacteria were maintained in TSB containing 20% glycerol and kept at -80°C for long term storage.

##### 4.2.4.1. Agar Diffusion Method

The bacteria which were used in agar diffusion studies were *Pseudomonas aeruginosa*, *Acinetobacter haemolyticus*, *Escherichia coli* O157:H7, *Salmonella* Enteritidis, *Staphylococcus epidermidis*, Methicillin Resistant *Staphylococcus aureus* (MRSA), Methicillin Susceptible *Staphylococcus aureus* (MSSA), and *Listeria monocytogenes*. In all agar diffusion experiments, the bacterial lawn was prepared according to the protocol below:

A single colony of the bacteria was inoculated into 4 ml of TSB media and incubated at 37°C for 18 hours to obtain overnight cultures. A 100 µl of the overnight culture was spreaded onto TSA media and allowed to dry for 1 hour at room temperature for agar diffusion tests.

To determine the antimicrobial effects, 15 µl of each solution (3 mg/ml-3-HPAA-Alg-Chi or 2.8 mg/ml-4-HBA-Alg-Chi and the respective phenolic acids solutions (in ddH<sub>2</sub>O) in the same concentrations) were tested by direct application on the agar plate. Nanoparticles and phenolic acid solutions were tested after treating with 1% (v/v) acetic acid in ddH<sub>2</sub>O for 24 hours at +4°C before application or without acetic acid treatment.

In addition, the higher concentrations of 3-HPAA were tested to determine the most effective concentration on bacteria by agar diffusion. According to these results, 25 mg/ml 3-HPAA loaded nanoparticles were produced with the aforementioned nanoparticle production protocol, and were tested on bacteria in 15 µl volume on agar directly. The nanoparticles were treated with 1% acetic acid in ddH<sub>2</sub>O, incubated for 24 hours and 72 hours at +4°C before application (for 25 mg/ml 3-HPAA-Alg-Chi solution).

#### **4.2.4.2. The Effect of the Nanoparticles on Bacterial Growth**

The bacteria which were used in these studies were *Pseudomonas aeruginosa*, *Staphylococcus epidermidis*, Methicillin Resistant *Staphylococcus aureus* (MRSA), and Methicillin Susceptible *Staphylococcus aureus* (MSSA). A single colony of the bacteria was inoculated into 4 ml of TSB and incubated at 37°C for 18 hours. The tubes containing 4 ml of total volume of the mixture of TSB, Alg-Chi nanoparticle solutions (null or 3-HPAA-Alg-Chi) with 10% or 20% (v/v) final concentrations and 1% (v/v) acetic acid (final concentration) were inoculated with 10<sup>6</sup> cfu/ml final bacterial load. The effect of 1% (v/v) acetic acid (final concentration) was simultaneously tested with the same concentrations with addition of ddH<sub>2</sub>O instead of nanoparticle solution. The optical density (O.D.) of the cultures were measured spectrophotometrically at 600 nm at the time of inoculation (hour 0) and at the end of the incubation period (hour 24). The cell viabilities of these cultures were also determined by enumeration studies.

### **4.3. Results and Discussion**

To investigate the possible application route of encapsulated phenolic acid solutions in the microbiological point of view, the alginate-chitosan nanoparticles (null or phenolic acid loaded) were produced, characterized and antimicrobially tested on various pathogenic bacteria *in vitro*.

#### **4.3.1. Investigation of Properties of Nanoparticles**

The polydispersity indexes (PDI), average diameters and distributions of number of all Alg-Chi nanoparticles were investigated by dynamic light scattering (DLS). The infrared spectra of the compounds were determined by Fourier Transform Infrared Spectroscopy (FT-IR) for comparison of physico-chemical properties of alginate, chitosan, 3-HPAA, 4-HBA, null Alg-Chi, 3-HPAA-Alg-Chi (3 mg/ml or 25 mg/ml 3-HPAA loaded) and 4-HBA-Alg-Chi (2.8 mg/ml 4-HBA loaded). To visualize the morphologies of null Alg-Chi, 3-HPAA-Alg-Chi (3 mg/ml or 25 mg/ml 3-HPAA loaded) and 4-HBA-Alg-Chi (2.8 mg/ml 4-HBA loaded), scanning electron microscopy (SEM) was used.

#### 4.3.1.1. Dynamic Light Scattering of Alg-Chi Nanoparticles

The results of DLS indicated the increase in the average size of Alg-Chi nanoparticles which indicates the successful encapsulation of 3-HPAA and 4-HBA. The size distributions of 3 mg/ml or 25 mg/ml 3-HPAA-Alg-Chi indicated the shift of the peaks of 3-HPAA-Alg-Chi were further to the right than null nanoparticles (Figures 4.1 a and b) while a minor shift of the peak was determined for 4-HBA-Alg-Chi compared to null nanoparticles (Figure 4.1 c). This might contributed to different physico-chemical properties of 3-HPAA and 4-HBA. Consequently, phenolic acid loaded nanoparticles have bigger average sizes than those of null ones. Since a single peak occurred for each solution, particle sizes had a high uniformity (Mohammadi et al., 2016).

Related to that, the average sizes of null nanoparticles were shown to be smaller than these of phenolic acid loaded nanoparticles (Table 4.1). For instance, 25 mg/ml 3-HPAA-Alg-Chi were determined as  $278.8 \pm 12.4$  nm and  $361.0 \pm 69.8$  nm for null and 3-HPAA-Alg-Chi, respectively (Table 4.1). Additionally, 3 mg/ml 3-HPAA-Alg-Chi had  $291.1 \pm 0.5$  nm and 4-HBA-Alg-Chi had  $316.0 \pm 3.8$  nm while null nanoparticles had  $255.8 \pm 2.3$  nm average diameters (Table 4.1). According to these results, the loading of 3-HPAA or 4-HBA into nanoparticles considered as successful. The loading the lower concentrations of phenolic acids resulted in the narrowest size distribution: the standard deviation was  $\pm 0.5$  for 3 mg/ml 3-HPAA while it was  $\pm 69.8$  when 25 mg/ml 3-HPAA was loaded (Table 4.1).

In addition, the distribution of size of null nanoparticles and phenolic acid nanoparticles were narrow (Table 4.1). Null nanoparticles had smaller diameters than 25 mg/ml 3-HPAA-Alg-Chi with narrower size distribution:  $\pm 12.4$  standard deviation for null and  $\pm 69.8$  for 25 mg/ml 3-HPAA-Alg-Chi (Table 4.1). It might be speculated that the protocol of nanoparticle production supported the homogeneous particles. However, loading with phenolic acids caused the homogeneity of the particles to decrease slightly depending on the concentration of loading compound used.

Additionally, it could be recognized that the average diameters of the nanoparticles were determined higher than 100 nm in DLS. Since the hydrodynamic diameters of the particles are measured in DLS technique (Krausz et al., 2015) and these values are the distribution in sizes, these higher diameters were expected. To be able to

determine exact diameters, the measurement of the diameters of particles in scanning electron microscopy could be examined.

Table 4.1. Comparison of average diameters (nm) and PDI values of null and phenolic acid loaded Alg-Chi nanoparticles via DLS.

Sample Name	PDI	Average Diameter (nm)
Null Nanoparticles	0.25	255.8 ±2.3
3-HPAA-Alg-Chi (3mg/ml)	0.27	291.1±0.5
Null Nanoparticles	0.22	278.8±12.4
3-HPAA-Alg-Chi (25 mg/ml)	0.23	361.0±69.8
Null Nanoparticles	0.25	255.8 ±2.3
4-HBA-Alg-Chi (2.8 mg/ml)	0.29	316.0 ±3.8

The polydispersity index (PDI) is another important parameter of size distribution. A decreased PDI value indicates an increase in the particle size homogeneity. Small PDI values (PDI <1) shows narrow size distributions (Liu et al., 2018; Qi et al., 2004).

In addition, PDI values must be below 0.7 for a nanoparticle sample to be suitable for DLS analysis (Dynamic Light Scattering Common Terms Defined, Malvern Instruments Manual; www.malvern.com). Since the PDI values of nanoparticles were about 0.2 for each nanoparticle solution (Table 4.1), all nanoparticle solutions were suitable for DLS analysis and it could be accepted that nanoparticle solutions were homogenous with similar homogeneity patterns.

#### 4.3.1.2. SEM Images of Alg-Chi Nanoparticles

According to the scanning electron micrographs, the produced null nanoparticles (Figure 4.2) were spherical. Also the same spherical structures were observed in the nanoparticles which were loaded with 3 mg/ml, 25 mg/ml 3-HPAA and 2.8 mg/ml 4-HBA (Figures 4.5, 4.6 and 4.7, respectively). The agglutinations of nanoparticles in the figures were expected based on the natural properties of chitosan based particles to produce agglomerates (Jamil et al., 2016 (b)).

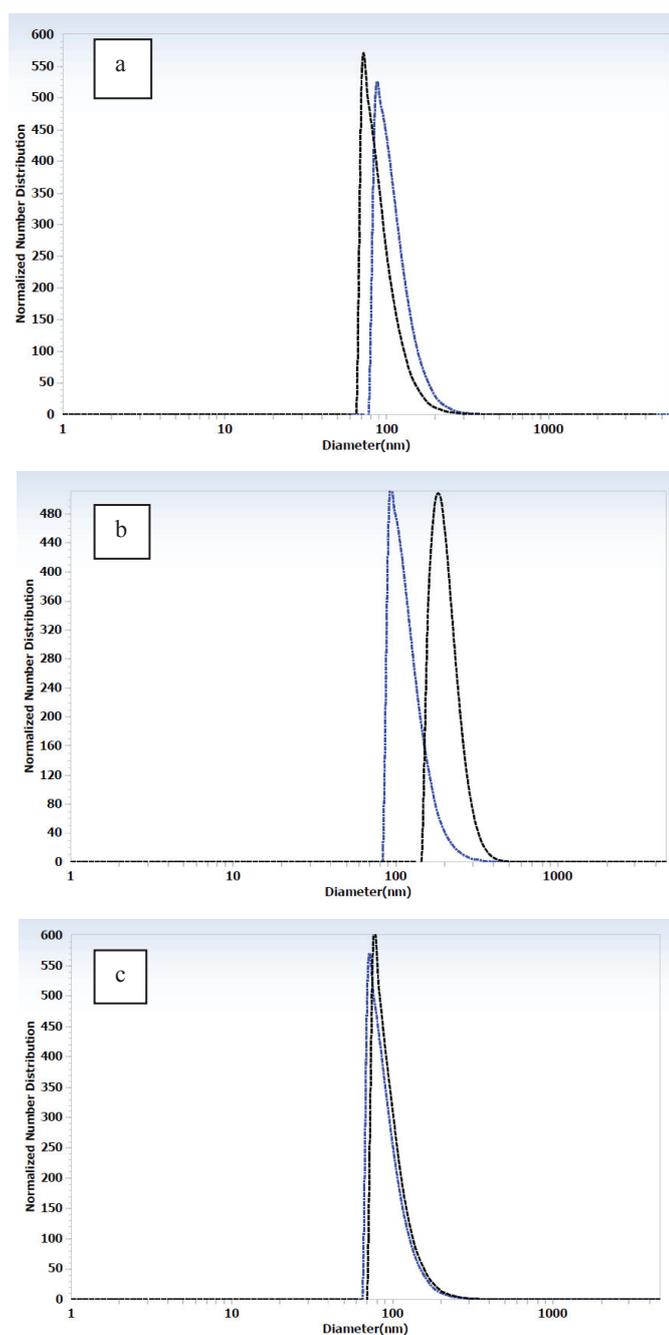

Figure 4.1. Normalized number distribution graphs of null and phenolic acid loaded Alg-Chi. a) 3 mg/ml 3-HPAA-Alg-Chi (Black peak: Null nanoparticles, Blue peak: 3-HPAA-Alg-Chi); b) 25 mg/ml 3-HPAA-Alg-Chi (Black peak: 3-HPAA-Alg-Chi, Blue peak: Null Nanoparticles); c) 4-HBA-Alg-Chi (Black peak: 4-HBA-Alg-Chi, Blue peak: Null Nanoparticles)

The chitosan nanoparticles are inclined to agglomerate depending on the domination of van der Waals attractive forces over repulsive forces (Jamil et al., 2016 (b)). According to the SEM images, the nanoparticles display homogenous sizes. In addition, the measurements of the diameters that were carried out at the time of SEM analyses via SEM instrument presented that the particles have diameters in a range of 25-40 nm for null, 3 mg/ml 3-HPAA-Alg-Chi and 2.8 mg/ml 4-HBA-Alg-Chi while 40-70 nm for 25 mg/ml 3-HPAA-Alg-Chi. Our results were consistent with the results of Azevedo et al. of which the production protocol of nanoparticles was used, since they also presented that the shapes of the nanoparticles they produced were spherical (Azevedo et al., 2014). However, the nanoparticles they produced were not homogeneous in sizes under TEM analysis. Since the particles of ours seem to display more homogeneous sizes under SEM, it could be speculated that the usage of increased molarity of  $\text{CaCl}_2$  in the production process might result in the production of more homogeneous nanoparticles.

#### **4.3.1.3. FTIR Analysis of Alg-Chi Nanoparticles**

The FT-IR results were shown in the Figures 4.8 and 4.9 for 25mg/ml- or 3 mg/ml-3-HPAA-Alg-Chi and 4-HBA-Alg-Chi, respectively. When the spectra were investigated, the differences in the wavelengths of the peaks could be recognized for each loaded nanoparticle type in comparison to null nanoparticles, chitosan, alginate and phenolic acid spectra. The differences in wavenumbers of peaks occurred especially in the region below  $1500\text{ cm}^{-1}$  which is the fingerprint region of FT-IR spectrum (Hynes et al., 2005).

These differences show that the compounds tested have different structures because of the new bond formations in the null or phenolic acid loaded nanoparticles productions. In addition, the spectra of 3-HPAA-Alg-Chi were the same regardless of the loaded concentrations of 3-HPAA and their spectra differ from that of 4-HBA-Alg-Chi. Since each compound had a unique FT-IR spectra, successful productions of nanoparticles as well as successful loading of phenolic acids into nanoparticles were achieved. The discussions about the structural changes were performed by comparing the peak wavelengths of the aforementioned samples obtained from Spectrum programme to the similar studies in the literature.

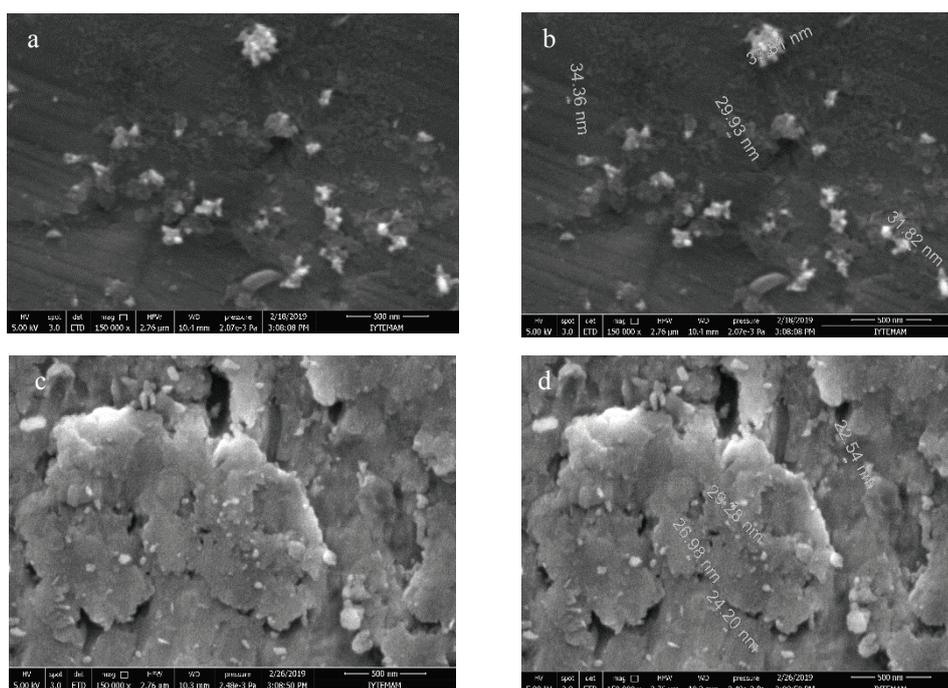

Figure 4.2. Morphologies of null Alg-Chi. a,b) The null nanoparticles which were produced in the study of 3 mg/ml 3-HPAA-Alg-Chi or 2.8 mg/ml 4-HBA-Alg-Chi; c, d) The null nanoparticles which were produced in the study of 25 mg/ml 3-HPAA-Alg-Chi at 150,000 x magnification. The diameters of the particles were determined at the time of SEM analysis.

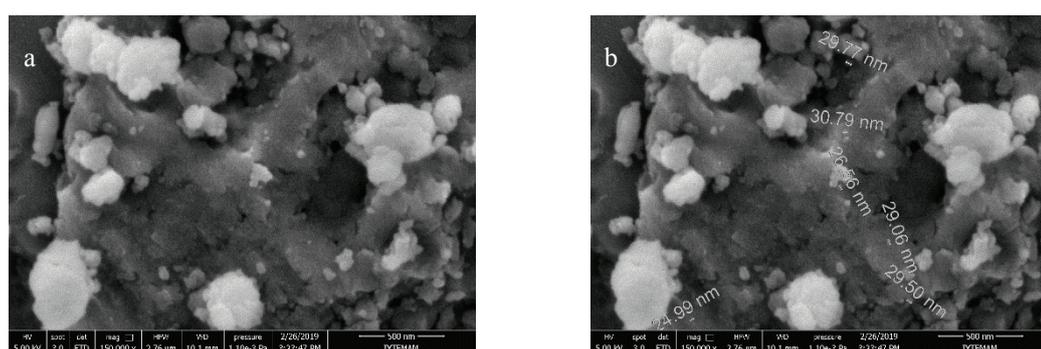

Figure 4.3. Morphologies of 3 mg/ml-3-HPAA-Alg-Chi (a) and the diameters of the particles (b) at 150,000 x magnification. The diameters were determined at the time of SEM analysis.

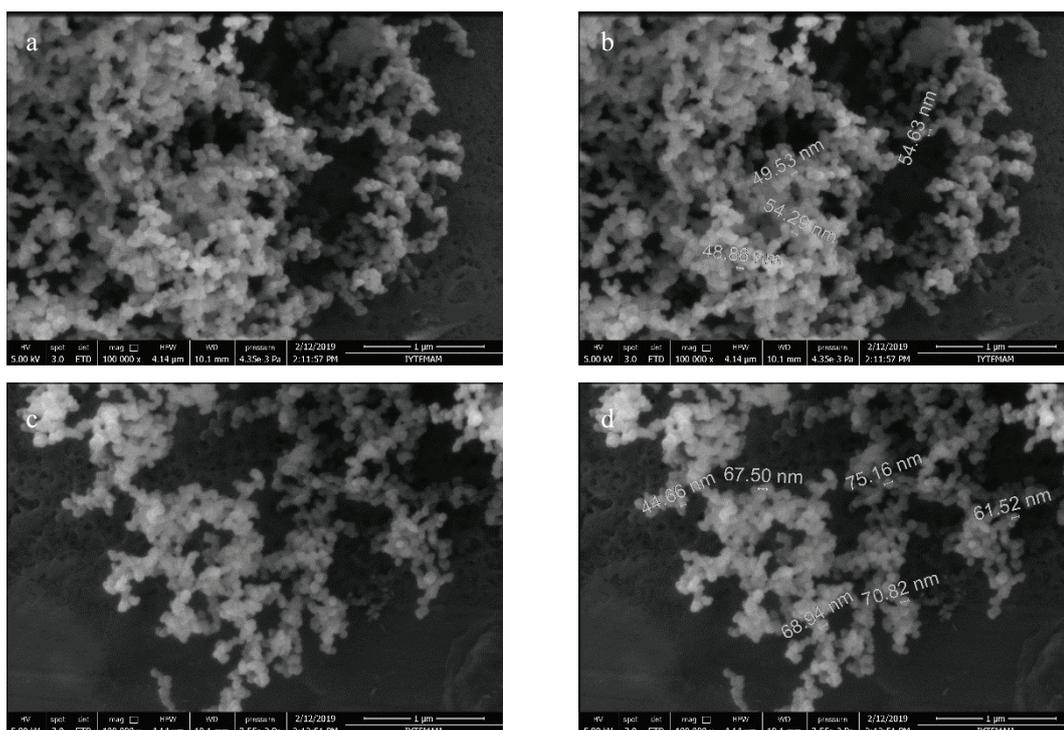

Figure 4.4. Morphologies of 25 mg/ml-3-HPAA-Alg-Chi (a and c) and the diameters of the particles (b and d) at 100,000 x magnification. The diameters were determined at the time of SEM analysis.

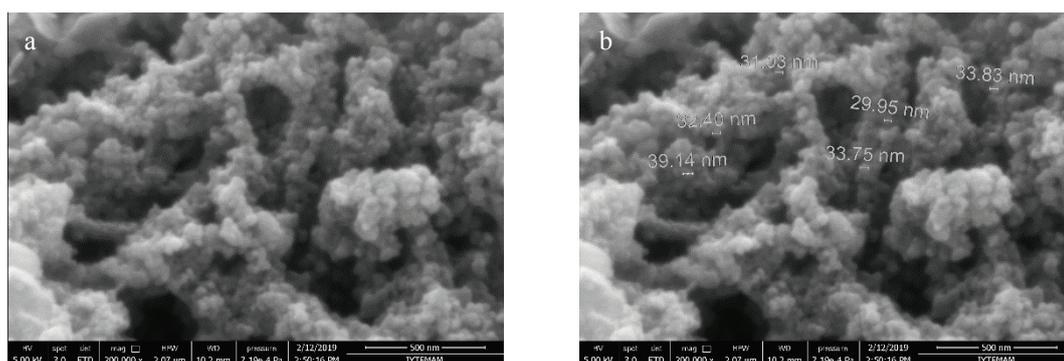

Figure 4.5. Morphologies of 2.8 mg/ml 4-HBA-Alg-Chi (a) and the diameters of the particles (b) at 200,000 x magnification. The diameters were determined at the time of SEM analysis.

The peaks of loaded nanoparticles at  $3196\text{ cm}^{-1}$  (Figure 4.6. a),  $3241\text{ cm}^{-1}$  (Figure 4.6. b), and  $3376\text{ cm}^{-1}$  (Figure 4.6. c), and null nanoparticles at  $3264\text{ cm}^{-1}$  (Figure 4.6. a and b), and  $3265\text{ cm}^{-1}$  (Figure 4.6. c), nanoparticles contain hydroxyl groups. These were caused from oxial O-H and N-H stretching of Chi at  $3288\text{ cm}^{-1}$  (Figure 4.6. a and b) and  $3289\text{ cm}^{-1}$  (Figure 4.6. c) and O-H stretching of Alg at  $3240\text{ cm}^{-1}$  (Figure 4.6. a and b) and  $3241\text{ cm}^{-1}$  (Figure 4.6. c) (Wu et al., 2018).

Additionally, the peak of null nanoparticles at  $3264\text{ cm}^{-1}$  (Figure 4.6. a and b) shifted to lower wavenumbers in 3-HPAA-Alg-Chi:  $3196\text{ cm}^{-1}$  for 3 mg/ml 3-HPAA-Alg-Chi,  $3241\text{ cm}^{-1}$  for 25 mg/ml 3-HPAA-Alg-Chi (Figure 4.6). Differently from 3-HPAA, in 4-HBA-Alg-Chi the wavenumber of null nanoparticles at  $3265\text{ cm}^{-1}$  was shifted to higher wavenumber  $3376\text{ cm}^{-1}$  because of different physico-chemical properties of these nanoparticles (Figure 4.7). These shifts in wavenumbers of peaks presented the successful loading of phenolic acids into alginate-chitosan nanoparticles (Wu et al., 2018). Another indicator of loading of 3-HPAA could be accepted as the disappearance of CH stretching of 3-HPAA compound at  $2965\text{ cm}^{-1}$  (Barrera-Necha et al., 2018) in 3-HPAA-Alg-Chi (Figure 4.6).

In Figure 4.6, the shifting of the peaks at  $1558\text{ cm}^{-1}$  in null nanoparticles could be seen towards the higher wavenumbers,  $1696\text{ cm}^{-1}$  and  $1698\text{ cm}^{-1}$  for 3 mg- and 25 mg/ml-3-HPAA-Alg-Chi, respectively. Similarly, in the 4-HBA-Alg-Chi spectra (Figure 4.7), the same peak at  $1558\text{ cm}^{-1}$  in null nanoparticles was shifted to  $1673\text{ cm}^{-1}$ . This was arised from electrostatic interactions which occur between the amine group of chitosan at  $1648\text{ cm}^{-1}$  and carboxylate group of alginate at  $1597\text{ cm}^{-1}$  (Figures 4.8 and 4.9) (Wu et al., 2018).

According to Wu et al., the peak at  $1404\text{ cm}^{-1}$  in null alginate-chitosan nanoparticles was caused from the symmetric stretching in carboxylic acid groups of alginate and chitosan (Wu et al.,2018). In our study, this peak was seen at  $1407\text{ cm}^{-1}$  in null nanoparticles (Figures 4.8 and 4.9) and its shift was obtained towards  $1386\text{ cm}^{-1}$  (Figure 4.6 a)  $1385\text{ cm}^{-1}$  (Figure 4.6 b) and  $1412\text{ cm}^{-1}$  (Figure 4.7) in 3 mg/ml-3-HPAA-Alg-Chi, 25 mg/ml-3-HPAA-Alg-Chi and 4-HBA-Alg-Chi. This shifting showed the loading of 3-HPAA or 4-HBA into the alginate-chitosan nanoparticles since they differ from null nanoparticles. Depending on the stretching vibrations of C-O-C of the polysaccharide structure, the peaks were obtained at  $1027\text{ cm}^{-1}$  and  $1026\text{ cm}^{-1}$  for chitosan and alginate, respectively (Liu et al., 2018).

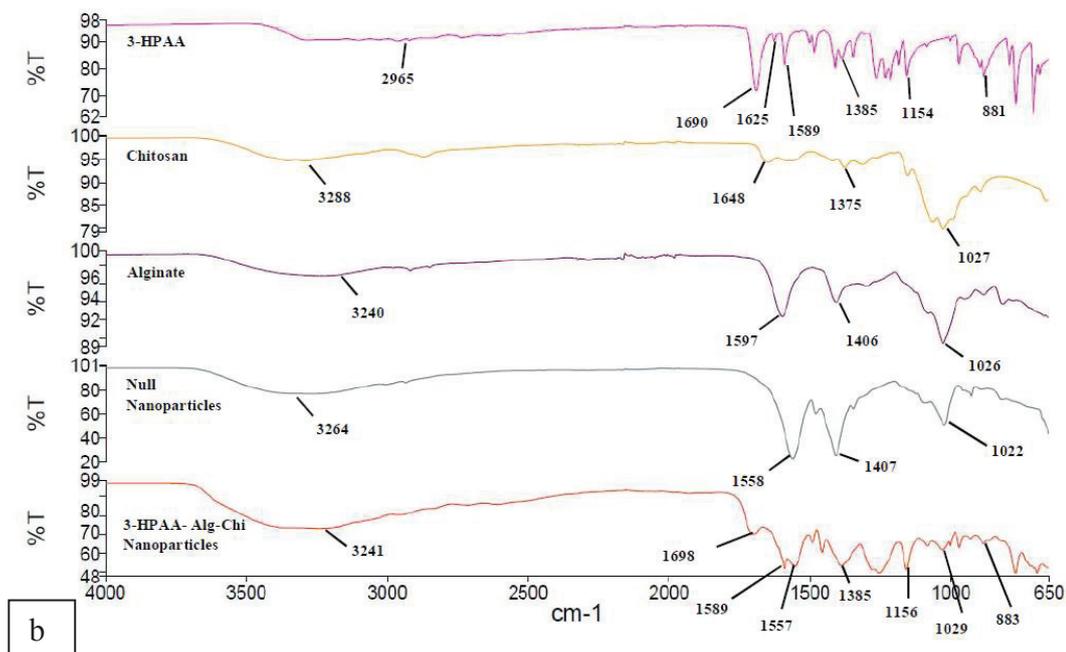

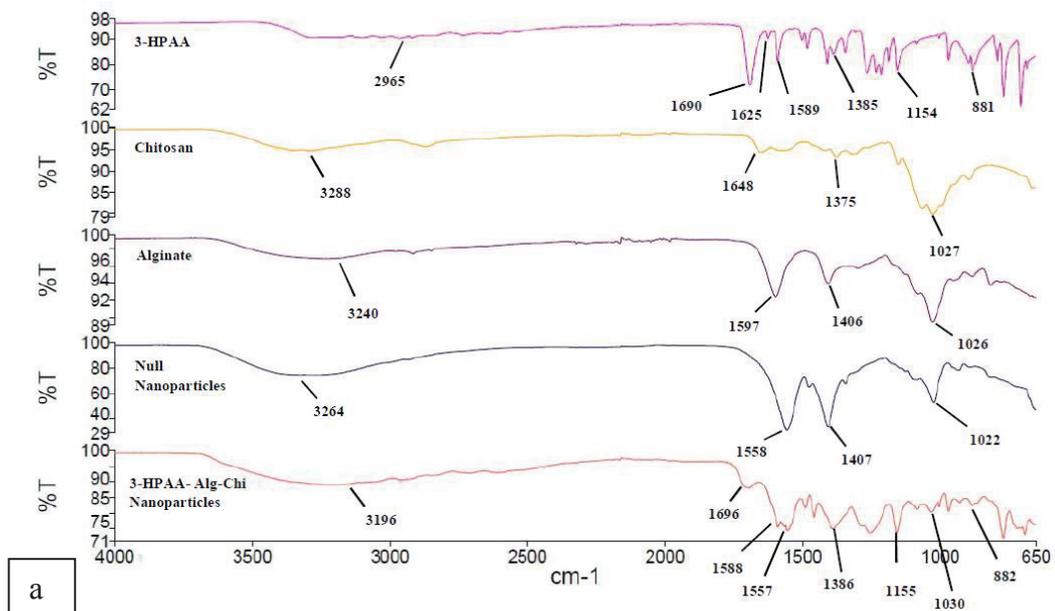

Figure 4.6. Comparison of the FT-IR spectra of the compounds in mid-IR region for 3 mg/ml (a) and 25 mg/ml (b) 3-HPAA-Alg-Chi. Different colors were used for the spectrum of each compound: 3-Hydroxyphenylacetic Acid (3-HPAA) (pink); Chitosan (yellow); Alginate (purple); Null Nanoparticles (grey) and 3-HPAA-Alg-Chi (orange)

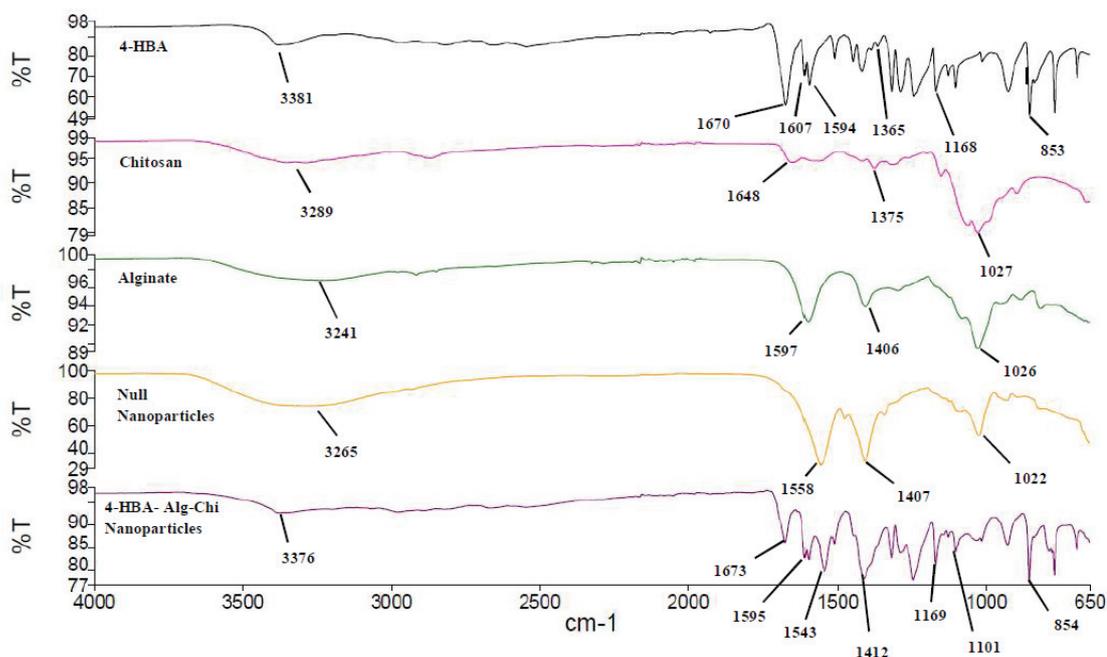

Figure 4.7. Comparison of the FT-IR spectra of the compounds in mid-IR region for 4-HBA-Alg-Chi. Different colors were used for the spectrum of each compound: 4-Hydroxybenzoic Acid (4-HBA) (grey); Chitosan (pink); Alginate (green); Null Nanoparticles (yellow) and 4-HBA -Alg-Chi (purple)

The peak which was related to C-O-C stretching was observed at  $1022\text{ cm}^{-1}$  in null nanoparticles and it was obtained at higher wavenumbers in phenolic acid loaded nanoparticles:  $1030\text{ cm}^{-1}$ ,  $1029\text{ cm}^{-1}$  and  $1101\text{ cm}^{-1}$  for 3 mg/ml-3-HPAA-Alg-Chi, 25 mg/ml-3-HPAA-Alg-Chi and 4-HBA-Alg-Chi, respectively (Figures 4.8 a, b and 4.9). This might show the bondings and chemical structure of each nanoparticle differentiated from each other and from alginate and chitosan.

Additionally, the peak at  $1154\text{ cm}^{-1}$  in 3-HPAA and at  $1168$  in 4-HBA corresponds to the asymmetric stretching of C-O-C bridge (Mladenovska et al., 2007). Since these peaks exist and slightly shifted to  $1155\text{ cm}^{-1}$  in 3 mg/ml 3-HPAA-Alg-Chi, to  $1156\text{ cm}^{-1}$  in 25 mg/ml 3-HPAA-Alg-Chi and to  $1169\text{ cm}^{-1}$  in 4-HBA-Alg-Chi, phenolic acid loading was successfully obtained (Figures 4.8 and 4.9).

Likewise, the peaks at  $881\text{ cm}^{-1}$  in 3-HPAA and at  $853\text{ cm}^{-1}$  in 4-HBA, which might demonstrate the aromatic ring (Barrera-Necha et al., 2018), were shifted to

slightly higher wavenumbers. These peaks were seen at  $882\text{ cm}^{-1}$  and  $883\text{ cm}^{-1}$  for 3 mg/ml 3-HPAA-Alg-Chi and 25 mg/ml 3-HPAA-Alg-Chi (Figures 4.8 a and b) and  $854\text{ cm}^{-1}$  for 4-HBA-Alg-Chi (Figure 4.7).

All in all, the comparison of the FT-IR spectra of null nanoparticles, phenolic acid loaded nanoparticles, phenolic acids, chitosan and alginate, indicated the successful production of null and phenolic acid loaded nanoparticles which show unique physico-chemical properties.

#### **4.4. Determination of Encapsulation Percentages**

After the specific wavelengths and standard graphs of phenolic acids were determined spectrophotometrically, the standard graphs were plotted and used in the encapsulation percentage calculations.

##### **4.4.1. Determination of UV-Visible Peaks of Phenolic Acids**

The wavelengths of the phenolic acids were determined based on the UV-Spectrum scanning of the diluted samples of phenolic acids. The spectrums of the phenolic acids were achieved in the range of 200-400 nm wavelengths in spectrophotometer.

The UV-Vis wavelength was demonstrated with 10-fold diluted 1 mg/ml stock solution of 3-HPAA (Figure 4.8 a). Since this phenolic acid had a significant peak at 270 nm, the wavelength for studies which were carried out with 3-HPAA was determined as 270 nm.

In the case of 4-HBA, the UV-Vis wavelength was demonstrated with 100-fold diluted 4-HBA stock solution (1 mg/ml) as demonstrated in Figure 4.8 b. The specific peak of this phenolic acid was observed at 250 nm. Thus, 250 nm was chosen as the wavelength for the studies of 4-HBA.

##### **4.4.2. The Standard Graphs of Phenolic Acids**

In the Figure.4.11 a and b, the standard curves of 3-HPAA and 4-HBA were shown, respectively. The graph of 3-HPAA has a  $R^2$  value of 0.9962 while that of 4-

HBA was 1 (Figure 4.9 a and b). The equations of these graphs, Equation 4.2 for 3-HPAA and Equation 4.3 for 4-HBA, were used for encapsulation percentage calculations of the phenolic acids.

The y value in these equations was the average absorbance value of supernatant while the x value show the concentration of phenolic acid in the supernatant at specific wavelength of each phenolic acid (Figure 4.9 a and b). The equations of the standart graphs were found as below:

$$y = 10.665x - 0.005 \quad (4.2)$$

$$y = 87.098x - 0.0057 \quad (4.3)$$

#### **4.4.3. Determination of Encapsulation Percentages**

The encapsulation percentages of 3-HPAA-Alg-Chi or 4-HBA-Alg-Chi were calculated based on the equations of standart graphs of the phenolic acids.

Centrifugation was performed prior to measurements to harvest the nanoparticles and to get rid of the impurities. Thus, the supernatant has the amount of phenolic acid that could not been encapsulated into nanoparticles. Table 4.2 demonstrates the average encapsulation percentages of 3-HPAA and 4-HBA into nanoparticles. As it is seen in Table 4.2, 3-HPAA or 4-HBA were loaded into nanoparticles with more than 99% encapsulation. Therefore, it was decided to test the nanoparticles in solution forms in the antimicrobial studies. The cross-linker, CaCl<sub>2</sub>, is one of the important parameters for the loading percentage, size and homogeneity of nanoparticles. The usage of higher concentrations of CaCl<sub>2</sub> in the nanoparticle production process results in the increased encapsulation percentage as well as the decreased average sizes and PDI values (Wu et al., 2018). Wu et al. demonstrated that higher encapsulation percentage, lower average size and PDI were obtained in the usage of 5 mM CaCl<sub>2</sub> when compared to those of 1 mM and 3 mM CaCl<sub>2</sub> usage in encapsulation of lysozyme into alginate-chitosan nanoparticles.

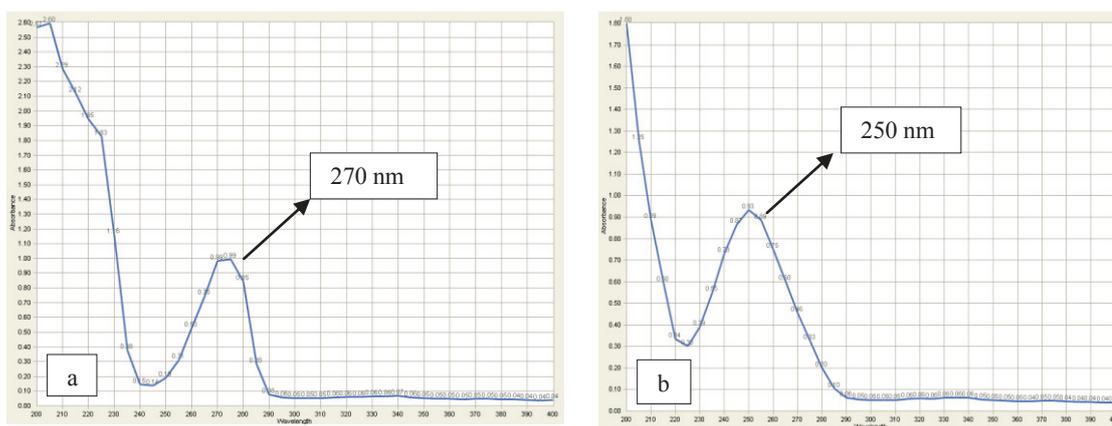

Figure 4.8. Graph of UV-spectrum scanning of phenolic acids. a) 3-HPAA (10-fold diluted from 1mg/ml stock solution in ddH<sub>2</sub>O) b) 4-HBA (100-fold diluted from 1mg/ml stock solution in ddH<sub>2</sub>O) (y axis: Absorbance, x axis: Wavelength).

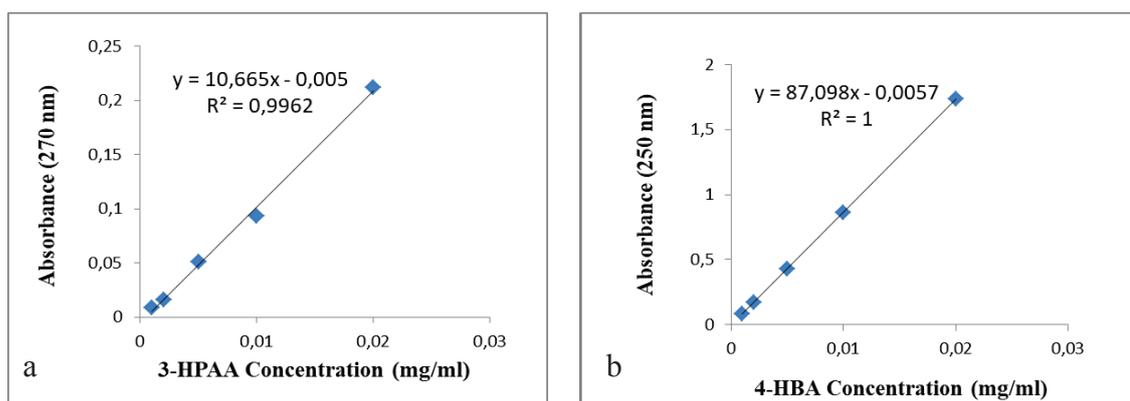

Figure 4.9. Standard graphs of phenolic acids. a) 3-HPAA b) 4-HBA

Table 4.2. The average encapsulation percentages of phenolic acids.

Sample	Concentration of Phenolic Acid in Supernatant (mg/ml)	Encapsulation Percentage (%)
3-HPAA-Alg-Chi (3 mg/ml)	0.23±0.002	99.6±0.31
3-HPAA-Alg-Chi (25 mg/ml)	0.28±0.017	99.9±0.04
4-HBA-Alg-Chi (2.8 mg/ml)	0.27±0.005	99.5±0.39

It was suggested that the increased concentration of CaCl<sub>2</sub> leads the increased cross-linking properties which result in fine pores and compact gelation of the polymers (Wu et al., 2018). In our study, the concentration of CaCl<sub>2</sub> was 25 mM. Thus, it could be concluded that, the obtained small and homogeneous alginate-chitosan nanoparticles with very high encapsulation percentages might be due to the usage of CaCl<sub>2</sub> in high concentration.

In the study of Madureira et al., phenolic acids (rosmarinic acid, protocatechuic acid or 2,5-dihydroxybenzoic acid) were encapsulated into chitosan nanoparticles with both high and low molecular weight chitosan (Madureira et al.,2015). Their results of low molecular weight chitosan are comparable to ours. They presented that the encapsulation percentages were in between 60-90% whereas it was found to be 99% in our study for each type of nanoparticles (Table 4.2). The usage of alginate for entrapping phenolic acids before covering with chitosan might enhance the encapsulation percentage in our study. In addition the cross-linker type (CaCl<sub>2</sub> in our study and tripolyphosphate in theirs) might cause the change in entrapment conditions. In addition to that, the simpler structure and different physico-chemical properties of 3-HPAA than those of rosmarinic acid, protocatechuic acid or 2,5-dihydroxybenzoic acid could cause higher encapsulation percentages in our study.

#### **4.4.4. Antimicrobial Tests of Nanoparticle Solutions**

The antimicrobial tests of nanoparticle solutions loaded with 3 mg/ml 3-HPAA or 2.8 mg/ml 4-HBA were performed with the comparison of free phenolic acid solutions in ddH<sub>2</sub>O with the same phenolic acid concentrations by agar diffusion (Figure 4.10 and 4.13). All solutions that contain acetic acid were applied after 24 hours of treatment with 1% acetic acid. These concentrations of phenolic acids were determined according to the antimicrobial studies of phenolic acids on *P. aeruginosa* which were performed previously (Appendix E).

The phenolic acid solutions without acetic acid treatment displayed no inhibition zones for tested Gram negative bacteria (Figure 4.10 a, c, e, g, regions III and V). When 1% acetic acid treated 4-HBA solution was tested, small and turbid inhibition zones for *P. aeruginosa*, *E.coli* O157:H7 and *S. Enteritidis* (Figure 4.10 a, e, g, region VI) and clear inhibition zone for *A. haemolyticus* (Figure 4.10 c, region VI) were observed. The

similar small and turbid inhibition zones were detected for 1% acetic acid treated 4-HBA loaded nanoparticle solution for the same aforementioned bacteria (Figure 4.10 b, f, h, region X) and a similar clear inhibition zone was observed for *A. haemolyticus* (Figure 4.10 d, region X). Therefore, 4-HBA loaded nanoparticles showed very slight effect on Gram negative bacteria except *A. haemolyticus*. Both 1% acetic acid and 1% acetic acid treated 4-HBA solutions (both free and nanoparticle) showed similar inhibition zones for this bacterium. The antimicrobial effect on *A. haemolyticus* might be due to the synergistic effect of acetic acid and tested solutions.

The 3-HPAA solution treated with 1% acetic acid did not produce any zones on Gram negative bacteria except *A. haemolyticus* (Figure 4.10 a, c, e, g, region IV). When the inhibition zones were compared in *A. haemolyticus* 1% acetic acid treated 3-HPAA-Alg-Chi solution (Figure 4.10 d, region IX) displayed bigger inhibition zones than that of 1% acetic acid treated 3-HPAA solution. However, the zones for phenolic acid loaded nanoparticle solutions as well as null nanoparticle solution were bigger and more clear (Figure 4.10 d, region VIII, IX, X). Thus, it might be concluded that nanoparticle solutions with 1% acetic acid treatment showed higher antimicrobial effect on *A. haemolyticus*. However, 3-HPAA-Alg-Chi solution treated with 1% acetic acid results in production of inhibition zones for other tested Gram negative bacteria. A better effect of this nanoparticle solution was detected for *S. Enteritidis* when compared to free 3-HPAA solution with 1% acetic acid (Figure 4.10 g, region IV and h, region IX). It could be concluded that, 3-HPAA-Alg-Chi solution treated with 1% acetic acid demonstrated slight antimicrobial effect on *P. aeruginosa* and *E. coli* O157:H7 while it showed higher antimicrobial effect on *A. haemolyticus* and *S. Enteritidis*. These results suggest that: The antimicrobial effect is depending on the type of the phenolic acid tested. The cell wall properties of the bacteria doesn't play any role in the antimicrobial effect of tested phenolic acids.

When the antimicrobial effects of all tested solutions were considered for Gram positive bacteria, it was clear that none of these solutions were effective on them. The application of the phenolic acids treated or untreated with 1% acetic acid and the nanoparticle solutions treated with 1% acetic acid result in no inhibition zones for *S. epidermidis*, MRSA, MSSA and *L. monocytogenes* as well as 1% acetic acid (Figure 4.11). Briefly, 3 mg/ml-3-HPAA-Alg-Chi and 4-HBA-Alg-Chi were slightly effective on some of the tested Gram negative bacteria while they have no inhibition effect on the

tested Gram positive bacteria. Treatment with 1% acetic acid increases the antimicrobial activity of the nanoparticle solutions depending on the pH change in Gram negative bacteria.

In addition, inside the inhibition zone of 70% ethanol, a ring-like growth of *Staphylococci* was observed. A further study was performed to test the effects of higher concentrations of ethanol on *Staphylococci* to determine the most effective ethanol concentration on these bacteria (Appendix F).

The increase in phenolic acid concentration could be useful for producing nanoparticle solutions with higher antimicrobial effects. Therefore, it was decided to use higher concentrations of phenolic acids in the production of loaded alginate chitosan nanoparticles. However, since the higher concentrations of 4-HBA was not dissolved properly in water, only 3-HPAA could be used in higher concentrations. The concentration of 3-HPAA which could produce inhibition zones on bacterial lawn was determined by agar diffusion experiment of 3-HPAA solutions (in ddH<sub>2</sub>O). The concentrations of 5, 10, 15, 20, 25 mg/ml of 3-HPAA were tested on each bacteria. Among Gram negative bacteria, the highest antimicrobial effect of 3-HPAA concentration range was observed for *A. haemolyticus*. The inhibition zones were clear for 20 and 25 mg/ml 3-HPAA while they were small and turbid for 10 and 15 mg/ml (Figure 4.12 b1 and b2, regions III, IV, V, VI). In the cases of *P. aeruginosa* and *S. Enteritidis*, 20 mg/ml 3-HPAA result in turbid zones and 25 mg/ml showed clear inhibition zones (Figure 4.12 a1, a2, d1, d2, regions V and VI). *E. coli* O157:H7 demonstrated turbid zones only with 25 mg/ml 3-HPAA (Figure 4.12 c1, c2, region VI). Thus, 25 mg/ml was the common concentration of 3-HPAA which show high antimicrobial effect among tested Gram negative bacteria. Among tested concentrations of 3-HPAA, only 25 mg/ml showed slight antimicrobial effect on *S. epidermidis* and *L. monocytogenes* (Figure 4.13 a1, a2, d1, d2, region VI). MRSA and MSSA could not be inhibited with any of the tested concentrations of 3-HPAA. As expected, phenolic acids demonstrated strain-specific and dose-dependent nature of antimicrobial effect in this study. Since the most effective concentration was determined as 25 mg/ml for most of the tested bacteria, it was chosen as the concentration of 3-HPAA for nanoparticle production.

The antimicrobial effects of 25 mg/ml-3-HPAA-Alg-Chi solution were demonstrated as well as null nanoparticle solution on Gram negative and Gram positive

bacteria in Figures 4.14 and 4.15, respectively. The effect of 1% acetic acid was also investigated because of its usage for dissolution of nanoparticles. The 1% acetic acid solution and null nanoparticle solutions with or without acetic acid treatment did not result in any inhibition zones for each bacterium (Figure 4.14 and 4.17, regions II, III, IV). However, both 1% acetic acid treated and untreated 25 mg/ml-3-HPAA-Alg-Chi solutions presented clear inhibition zones for the bacteria except MRSA and MSSA (Figures 4.16 and 4.17, regions V and VI). Smaller, clear inhibition zones of MRSA and MSSA were detected only in 1% acetic acid treated 25 mg/ml-3-HPAA-Alg-Chi solution applied regions (Figure 4.15 c, d, e, f, region VI).

According to these results, it could be concluded that the obtained antimicrobial effect might be due to the 3-HPAA existence in the nanoparticle solution, not to the alginate-chitosan or acetic acid. This emphasized antimicrobial effect of 3-HPAA-Alg-Chi could be related to the interactions of 3-HPAA with alginate and chitosan. In addition, in *P. aeruginosa*, *E. coli* O157:H7, *S. Enteritidis* and *S. epidermidis*, bigger and clearer inhibition zones were detected for 1% acetic acid treated 3-HPAA-Alg-Chi than those of untreated one. Since acetic acid provide the required pH change for dissolution of nanoparticles, higher antimicrobial effect of the solution was an expected consequence.

The observation of the inhibition zones only for 1% acetic acid treated 3-HPAA-Alg-Chi in both MRSA and MSSA indicates the enhancement of the antimicrobial effect of 3-HPAA via encapsulation. Previously, it was determined that 25 mg/ml 3-HPAA was not effective on MRSA and MSSA (Figure 4.13 b1, b2, c1, c2, region VI). However after encapsulation and 1% acetic acid treatment, the inhibition zones were detected for MRSA and MSSA (Figure 4.15, c, d, e, f, region VI) which demonstrate the elevated antimicrobial effect of bioactive compounds after encapsulation. Consistent with our results, in the two studies of Jamil et al. in 2016, and the study of Liu et al in 2018, the increase of antimicrobial effect by encapsulation was clearly shown (Jamil et al., 2016 (a); Jamil et al., 2016 (b), Liu et al., 2018). The kefzole loaded chitosan nanoparticles showed larger inhibition zones for *Klebsiella pneumoniae* and *Pseudomonas aeruginosa* with the increasing concentrations of drugs in nanoparticles while no inhibition zones were detected in the application of the antibiotics alone (Jamil et al., 2016 (a)). Jamil et al. also examined the increased antimicrobial effect of chitosan nanoparticles loaded with cardamom essential oil on growth of MRSA and *E. coli* (Jamil et al., 2016 (b)).

Although the bacterial growth inhibition was not observed in the presence of cardamom essential oil, the application of cardamom essential oil loaded chitosan nanoparticles result in the complete inhibition of growth of both MRSA and *E. coli*.

Likewise, Liu et al. demonstrated a three-fold increase in the antimicrobial effect of the alginate-chitosan nanoparticles loaded with  $\epsilon$ -polylysine than that of free  $\epsilon$ -polylysine on *E. coli*, *B. subtilis*, *S. aureus* and *M. luteus* (Liu et al., 2018). Our study was also showed the enhancement of the antimicrobial effects of bioactive compounds after encapsulation. In the study of Liu et al. in which the antimicrobial effects of null alginate-chitosan nanoparticles and  $\epsilon$ -polylysine loaded alginate-chitosan nanoparticles were tested on *E. coli*, *B. subtilis*, *S. aureus* and *M. luteus* (Liu et al., 2018). They indicated that in the application of  $\epsilon$ -polylysine loaded alginate-chitosan nanoparticles, significant inhibition zones were observed while in unloaded alginate-chitosan nanoparticle application no inhibition zones were observed similar to our results.

Another important point was the maintained antimicrobial effect of 3-HPAA-Alg-Chi after 24 hours or 72 hours of 1% acetic acid treatment. When the inhibition zones were compared for 24 hours and 72 hours of treatment with 1% acetic acid, a similar pattern was determined for each tested bacterium. Thus, it was concluded that the antimicrobial effect of 3-HPAA-Alg-Chi could be obtained after 24 hours of 1% acetic acid treatment. In addition, its antimicrobial properties were carried on even after 72 hours subsequent to treatment with 1% acetic acid (Figures 4.16 a,c,e,f and 4.17 b, d, f, g, region VI).

The growths of tested bacteria in the presence of nanoparticle solutions treated with 1% acetic acid were demonstrated in Figure 4.16. All tested solutions with the 10% (v/v) applications, inhibited the *P. aeruginosa* growth (Figure 4.16 a) with higher than 95% inhibitions (Table 4.3). However, the cell viability studies presented that the only solution which showed bacteriocidal effect (no survivors) on *P. aeruginosa* among the solutions tested in 10% (v/v) application was 3-HPAA-Alg-Chi (Table 4.3). In the case of *S. epidermidis*, the inhibition was observed only with the presence of 3-HPAA-Alg-Chi solution with 10% (v/v) concentration (Figure 4.16 b) as well as being bacteriocidal (Table 4.3). On the other hand, the application of 10% (v/v) concentration of 3-HPAA-Alg-Chi showed the highest antimicrobial effect among all the tested solutions with higher than 93% growth inhibition in MRSA and MSSA. These results were demonstrated in Table 4.3.

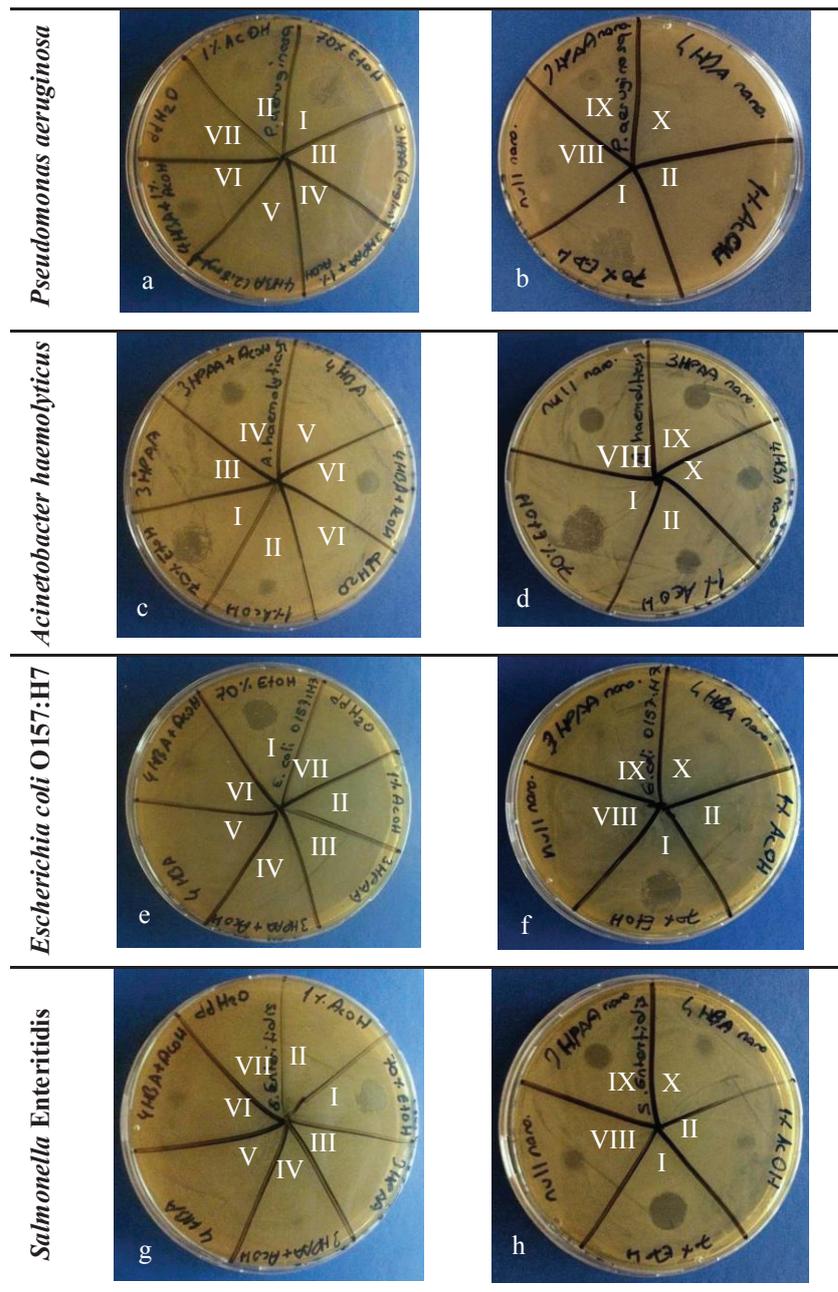

Figure 4.10. The effects of phenolic acid solutions (a, c, e, g) and phenolic acid loaded nanoparticle solutions (b, d, f, h) on Gram negative bacteria. *P. seruginosa* (a, b); *A. haemolyticus* (c, d); *E. coli* O157H:7 (e,f); *S. Enteritidis* (g, h). Each solution was indicated in a roman number as folllowing: 70% Ethanol (I); 1% Acetic acid (II); 3-HPAA in ddH<sub>2</sub>O (3mg/ml) (III); 3-HPAA in 1% acetic acid (3mg/ml) (IV); 4-HBA in ddH<sub>2</sub>O (2.8 mg/ml) (V); 4-HBA in 1% acetic acid (2.8 mg/ml) (VI); ddH<sub>2</sub>O (VII); Null nanoparticle solution (VIII); 3 mg/ml 3-HPAA-Alg-Chi solution (IX); 2.8 mg/ml 4-HBA-Alg-Chi solution (X).

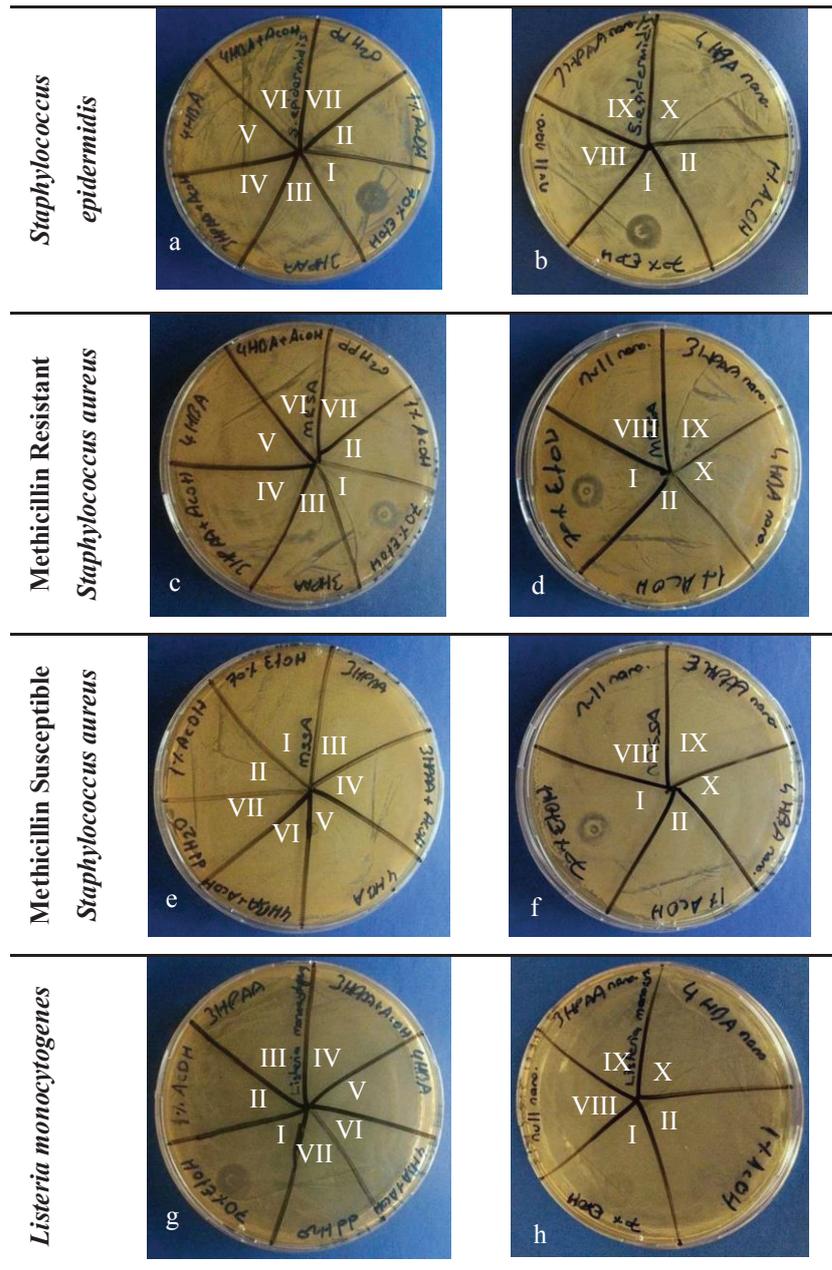

Figure 4.11. The effects of phenolic acid solutions (a, c, e, g) and phenolic acid loaded nanoparticle solutions (b, d, f, h) on Gram positive bacteria. *S. epidermidis* (a, b); MRSA (c, d); MSSA (e,f); *L. monocytogenes* (g, h). Each solution was indicated in a roman number as following: 70% Ethanol (I); 1% Acetic acid (II); 3-HPAA in ddH<sub>2</sub>O (3mg/ml) (III); 3-HPAA in 1% acetic acid (3mg/ml) (IV); 4-HBA in ddH<sub>2</sub>O (2.8 mg/ml) (V); 4-HBA in 1% acetic acid (2.8 mg/ml) (VI); ddH<sub>2</sub>O (VII); Null nanoparticle solution (VIII); 3 mg/ml 3-HPAA-Alg-Chi solution (IX); 2.8 mg/ml 4-HBA-Alg-Chi solution (X).

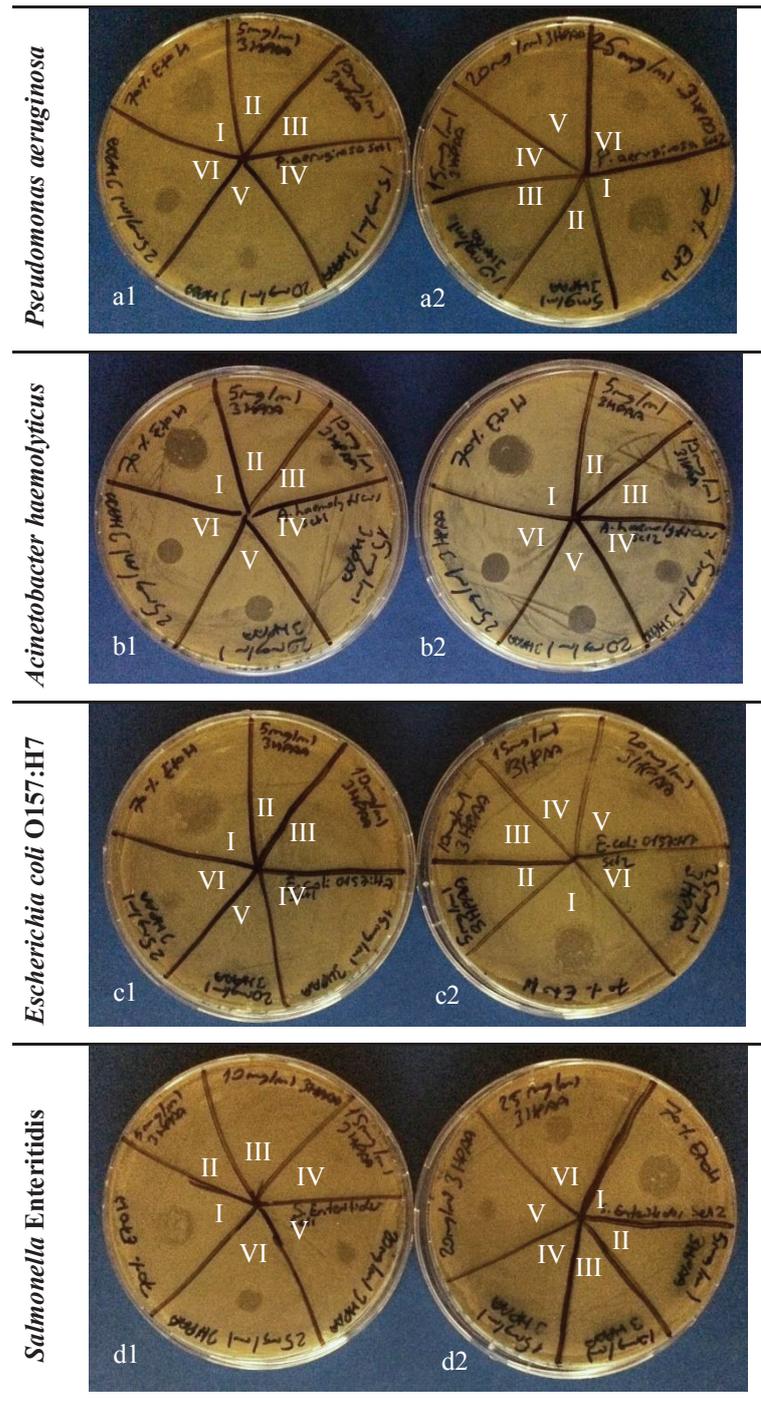

Figure 4.12. The effects of 3-HPAA solutions in a concentration range of 5-25 mg/ml (in ddH<sub>2</sub>O) on Gram negative bacteria. Each bacteria was presented as 2 sets: *P. aeruginosa* (a1, a2); *A. haemolyticus* (b1, b2); *E. coli* O157H:7 (c1, c2); *S. Enteritidis* (d1, d2). Each solution was indicated in a roman number as following: 70% Ethanol (I); 5 mg/ml 3-HPAA (II); 10 mg/ml 3-HPAA (III); 15 mg/ml 3-HPAA (3mg/ml) (IV); 20 mg/ml 3-HPAA (V); 25 mg/ml 3-HPAA (VI).

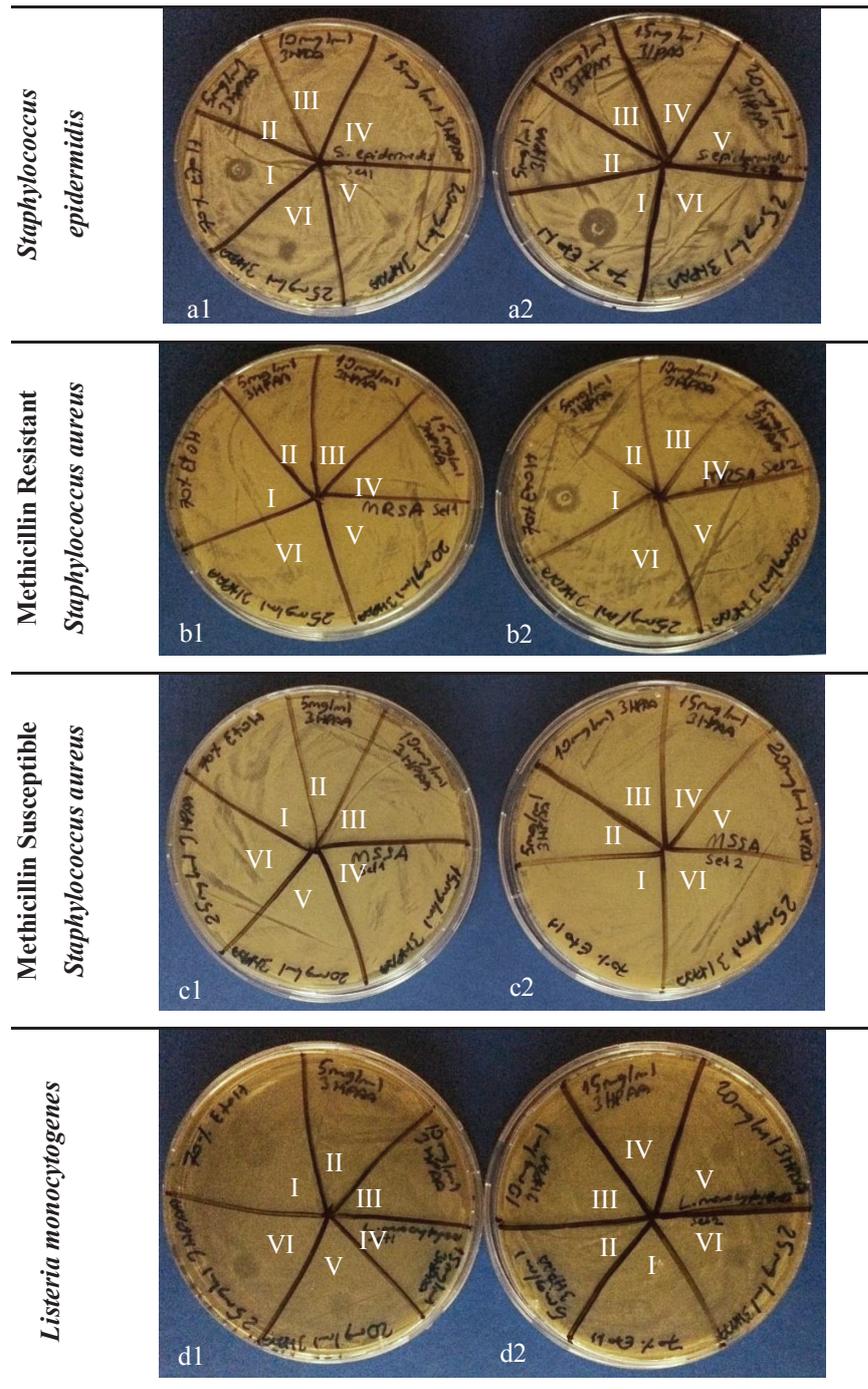

Figure 4.13. The effects of 3-HPAA solutions in a concentration range of 5-25 mg/ml (in ddH<sub>2</sub>O) on Gram positive bacteria. Each bacteria was presented as 2 sets: *S. epidermidis* (a1, a2); MRSA (b1, b2); MSSA O157H:7 (c1, c2); *Listeria monocytogenes* (d1, d2). Each solution was indicated in a roman number as following: 70% Ethanol (I); 5 mg/ml 3-HPAA (II); 10 mg/ml 3-HPAA (III); 15 mg/ml 3-HPAA (3mg/ml) (IV); 20 mg/ml 3-HPAA (V); 25 mg/ml 3-HPAA (VI).

Although 10% (v/v) concentration application caused only bacteriostatic effect (Figure 4.16 c, d), the 20% application displayed bacteriocidal effect on MRSA and MSSA (Figure 4.16 e, f). Although the result of 1% acetic acid application with 20% (v/v) final concentration showed significant antimicrobial effects different than that in our agar diffusion studies, it demonstrated the importance of the bacterial load on which the application done and the dose- dependent nature of antimicrobial agents. In the study of Jamil et al., it was also found that the antimicrobial effects of kefzole loaded chitosan nanoparticles presented different antimicrobial effects in agar diffusion and broth assays (Jamil et al., 2016 (a)). Similar to our results of acetic acid application, the lowest tested concentration in the agar diffusion tests, displayed much higher antimicrobial activity in the broth assays (Jamil et al., 2016 (a)).

All of these results indicated the antimicrobial effect of 3-HPAA was enhanced after encapsulation into alginate chitosan nanoparticles. In addition, 3-HPAA-Alg-Chi showed its antimicrobial effect on different bacteria with different levels: For the bacteriocidal effect on *P. aeruginosa* and *S. epidermidis* 10% (v/v) concentration was sufficient while 20% (v/v) concentration was required for MRSA and MSSA (Table 4.3). Consistent with our results, Madureira et al. demonstrated the growth inhibitions of various bacteria were changed between 60-90% in the presence of chitosan encapsulated rosmarinic acid (RA), protocatechuic acid (PA) and the 2,5-dihydroxybenzoic acid (DHBA) (Madureira et al., 2015).

These might display the strain-specific and dose-dependent properties of nanoparticles loaded with phenolic compounds in the case of their antimicrobial effects. The synergistic effect of 3-HPAA, alginate-chitosan and acetic acid might contribute the bacteriocidal effect of 3-HPAA-Alg-Chi solution. In addition, it showed bacteriostatic effect on the pathogenic bacteria with different concentrations regardless of their Gram properties. These results lead the conclusion that 3-HPAA-Alg-Chi solution might be studied in more detail as a promising antimicrobial agent for future usage.

#### **4.5. Overall Conclusions and Future Aspects**

This study presented that the water soluble phenolic acids 3-HPAA and 4-HBA showed high antimicrobial effects on *P. aeruginosa*, which is a serious pathogen.

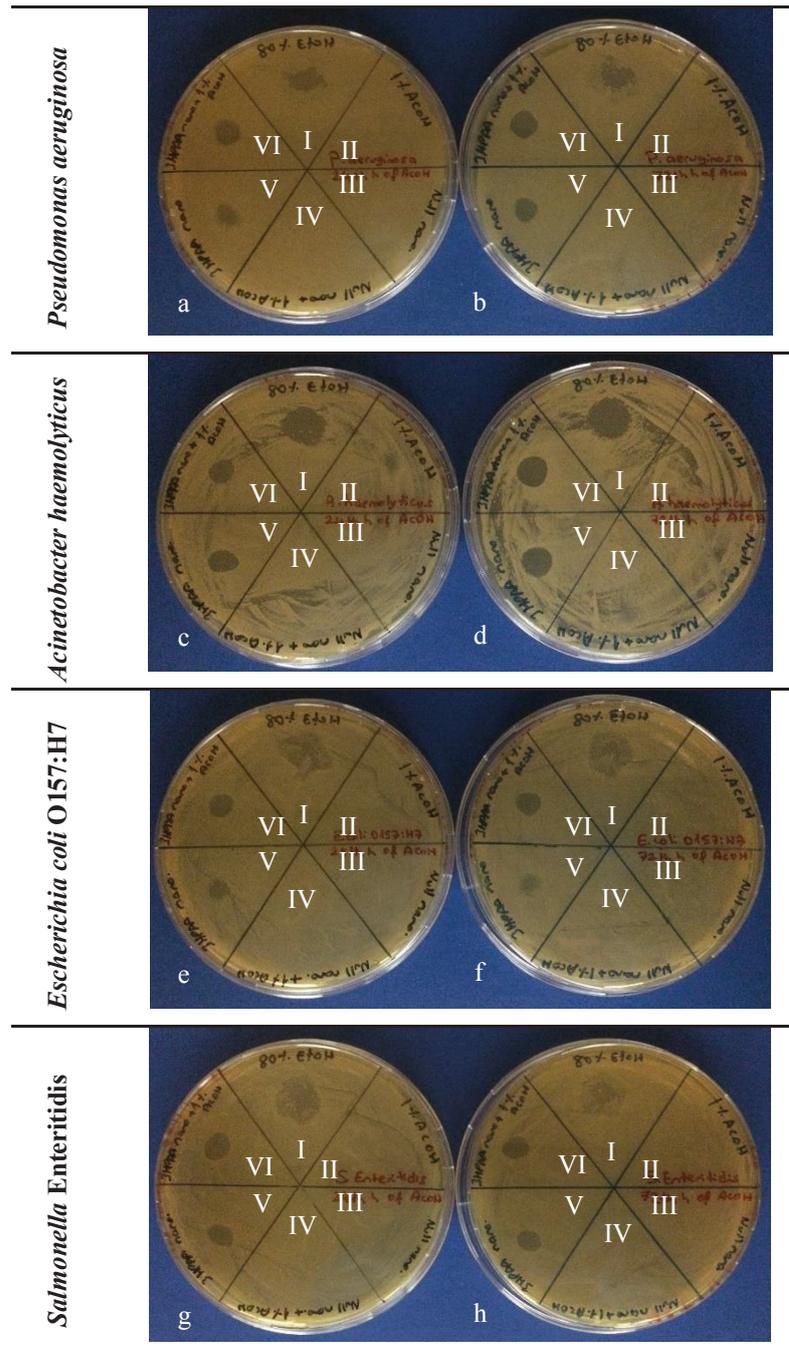

Figure 4.14. The effect of 25 mg/ml 3-HPAA loaded nanoparticles with or without acetic acid treatment for 24 (a, c, e, g) or 72 hours (b, d, f, h) on Gram negative bacteria. *P. seruginosa* (a, b); *A. haemolyticus* (c, d); *E. coli* O157H:7 (e, f); *S. Enteritidis* (g, h). Each solution was indicated in a roman number as following: 80% Ethanol (I); 1% Acetic acid (II); Null nanoparticle solution (III); Null nanoparticle solution in acetic acid (IV); 3-HPAA-Alg-Chi solution (V); 3-HPAA-Alg-Chi solution in acetic acid (VI).

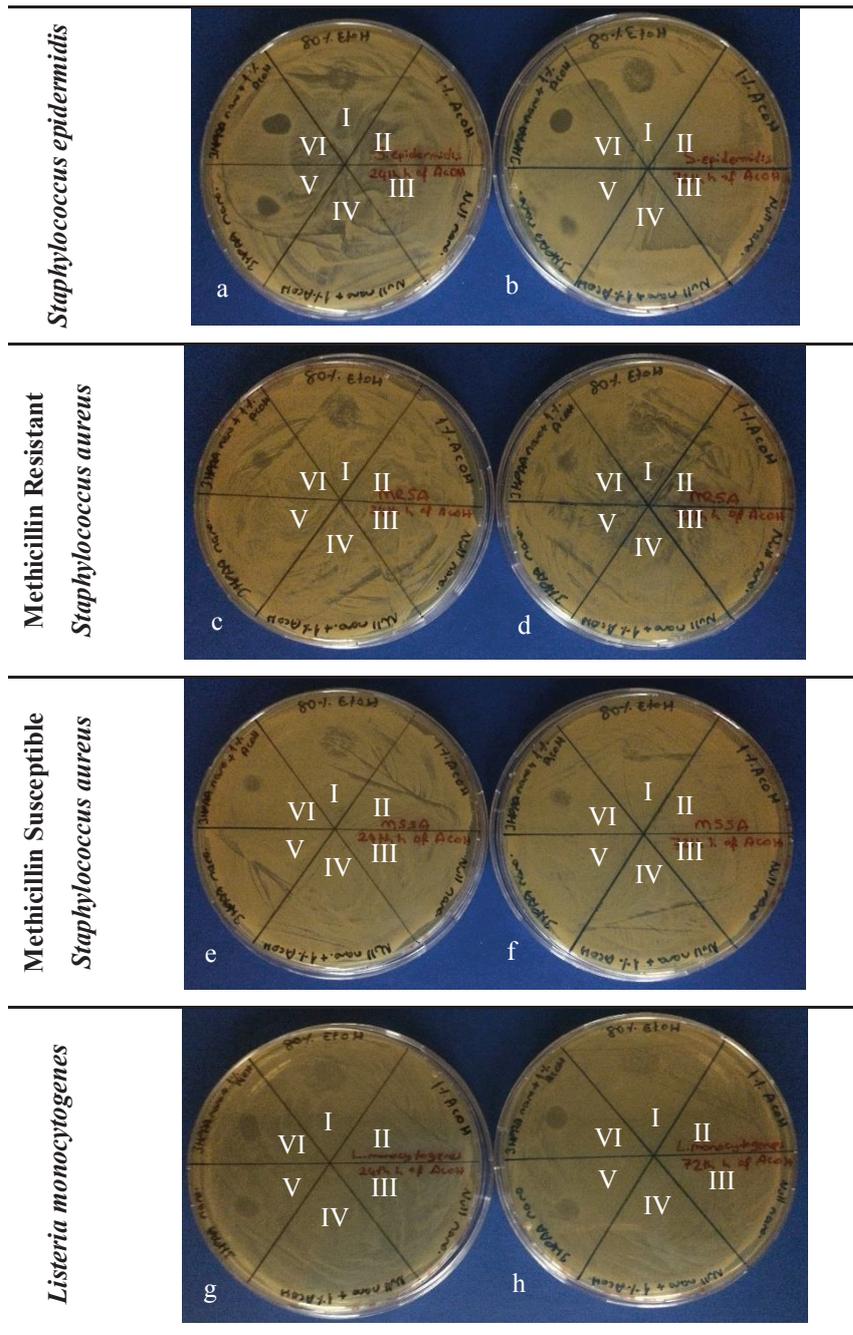

Figure 4.15. The effect of 25 mg/ml 3-HPAA loaded nanoparticles with or without acetic acid treatment for 24 (a, c, e, g) or 72 hours (b, d, f, h) on Gram positive bacteria. *S. epidermidis* (a, b); MRSA (c, d); MSSA (e, f); *L. monocytogenes* (g, h). Each solution was indicated in a roman number as following: 80% Ethanol (I); 1% Acetic acid (II); Null nanoparticle solution (III); Null nanoparticle solution in acetic acid (IV); 3-HPAA-Alg-Chi solution (V); 3-HPAA-Alg-Chi solution in acetic acid (VI).

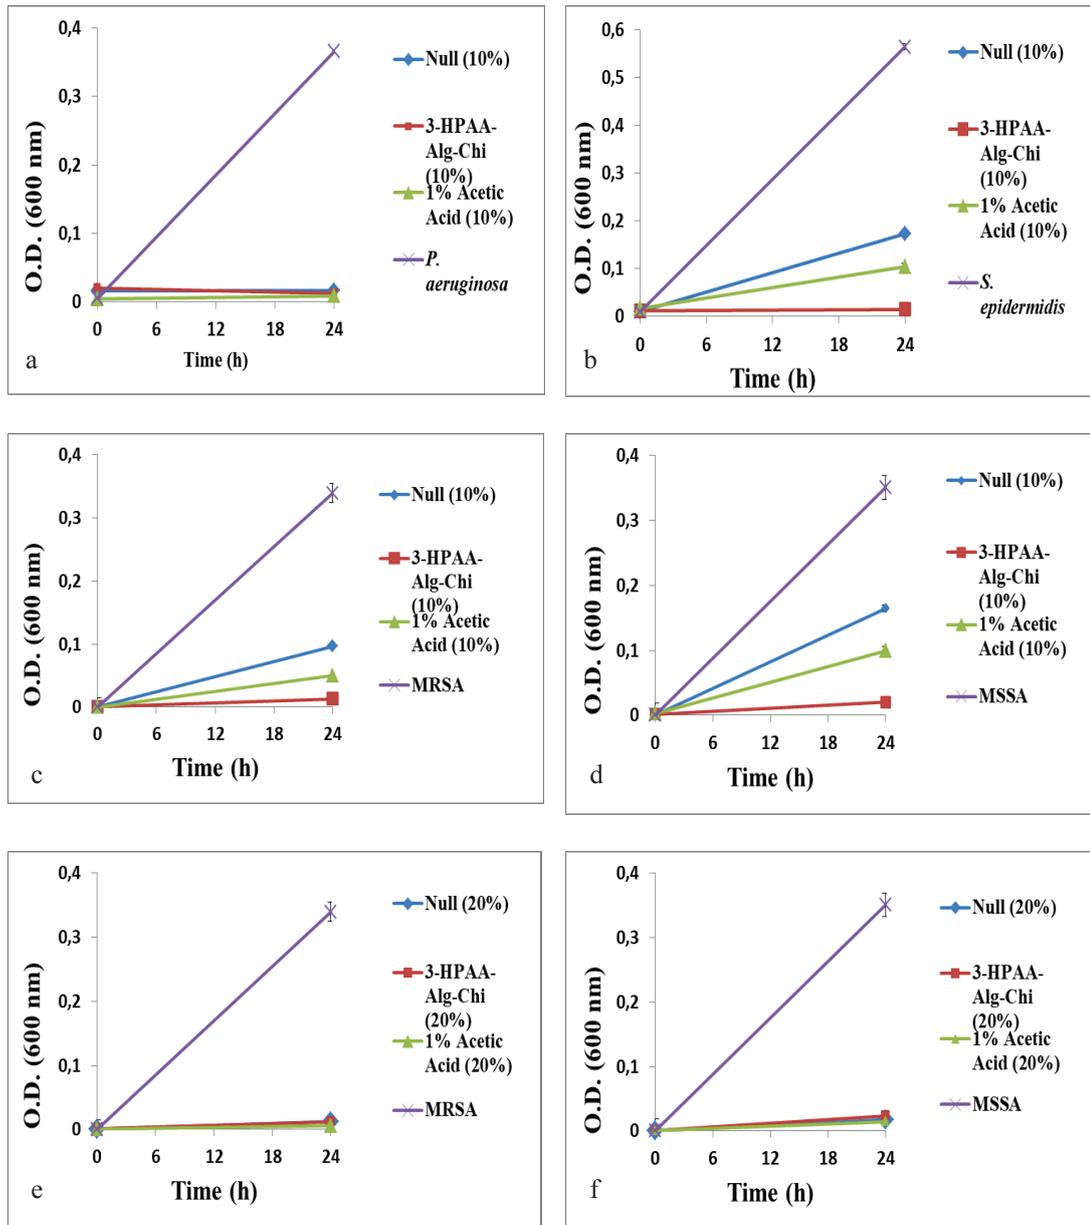

Figure 4.16. The antimicrobial effects of the nanoparticles and 1% acetic acid with 10% final concentration (a, b, c, d) and 20% final concentration (e, f) on bacterial growth of *P. aeruginosa* (a), *S. epidermidis* (b), MRSA (c, e) and MSSA (d, f). In each graph, the colors of lines correspond to the bacterial growth in the presence of the following: Null nanoparticles (blue); 3-HPAA-Alg-Chi (red); 1% acetic acid (green) and control bacteria (purple).

Table 4.3. Percent inhibitions and cfu/ml values of bacteria in the presence of nanoparticles in 10% or 20% volume application.

		Solutions	Percent Inhibition (%)	Cell viability (cfu/ml)
10% (v/v) APPLICATION	<i>P. aeruginosa</i>	Null nanoparticles	95	TMTC*
		3-HPAA loaded nanoparticles	97	No survivors
		Acetic acid (1%)	98	TMTC
	<i>S. epidermidis</i>	Null nanoparticles	69	TMTC
		3-HPAA loaded nanoparticles	97	No survivors
		Acetic acid (1%)	82	TMTC
	MRSA	Null nanoparticles	72	TMTC

		Acetic acid (1%)	85	TMTC
MSSA	Null nanoparticles	55	TMTC	
	3-HPAA loaded nanoparticles	94	TMTC	
	Acetic acid (1%)	73	TMTC	
20% (v/v) APPLICATION	MRSA	Null nanoparticles	96	TMTC
		3-HPAA loaded nanoparticles	96	No survivors
		Acetic acid (1%)	98	TMTC
	MSSA	Null nanoparticles	95	TMTC
		3-HPAA loaded nanoparticles	94	No survivors
		Acetic acid (1%)	96	TMTC

\*TMTC: Too many to count

The free forms of the phenolics showed bacteriostatic and bacteriocidal effects in a dose-dependent manner. In addition, the treatment of *P. aeruginosa* with the subinhibitory concentrations of each phenolic resulted in morphological changes in bacteria. The distinct greenish-blue color of *P. aeruginosa* culture was disappeared which could be recognized by naked eye and invaginations were formed on the surface of the bacterial cells which were determined in the SEM images. The bacteria which were grown in the presence of phenolic acids were elucidated at the proteomic level to determine the molecular reasons of the antimicrobial effects of the phenolics, including the reasons of the mentioned morphological changes. It was presented that the proteins functioned in the biosynthesis of phenazine pigment which gives the blue color of *P. aeruginosa* were not detected after phenolic acids exposure. Since this pigment is also an important virulence factor, it could be pointed out that not only the color but also the virulence of *P. aeruginosa* were reduced with phenolic acids. Besides that, the proteomic data revealed various changes in metabolic pathways which were mostly due to the adaptation process of the bacteria to the phenolic acid-containing environment. However, some notable changes in the protein profile of the bacteria could give clues about the affected processes of the bacteria after phenolic exposure. The proteomic study showed the changes in the bacterial cell membrane proteins which could be the reasons of invaginations of bacterial surfaces seen in SEM images. For instance, the various changes in the carboxypeptidases and endopeptidases as well as lipid metabolism related proteins might demonstrate that the bacteria managed to fix the defects in their membranes. Another important point was the changes in the RNA metabolism which includes the changes in tRNA biosynthesis related proteins and structural ribosomal RNA proteins. These might show that phenolic acids might result in the problems of biosyntheses and structures of tRNAs, rRNAs and ribosomes, thereby the protein translation. The undetection of iron homeostasis related proteins such as Fe(3+)-pyochelin receptor and the newly detection of phosphate starvation response protein PhoB might point out that the bacteria suffered from the nutrient starvation (iron and phosphate, respectively) which might lead to the inhibition of bacterial growth. The phenolic acids also seemed to result in serious oxidative stress with newly detection of various redox homeostasis related proteins including OxyR. Besides, it was demonstrated that the phenolic acid exposure caused changes in the DNA replication and repair mechanisms. Although each phenolic acid resulted in the

changes in DNA replication and repair mechanisms, especially 3-HPAA resulted in the undetection of proteins functioned in NER and MMR which might lead to the serious DNA damage. The bacteria might manage to carry out horizontal gene transfer via recombination for survival since recombination related proteins were newly detected. All of these results were speculated as the phenolic acids may show their antimicrobial effects by causing defects in more than one bacterial processes which makes them multi-target antimicrobial agents.

The phenolic acids also demonstrated the antimicrobial effects after encapsulation into alginate-chitosan nanoparticles on various pathogens. The usage of high molarity of cross-linker  $\text{CaCl}_2$  in nanoparticle production, resulted in the homogeneous nanoparticles with high encapsulation percentages. The phenolic acid loaded nanoparticles showed a dose- and strain-dependent bacteriostatic and/or bacteriocidal effects and the acetic acid treatment of the nanoparticle solutions 24 hours before their application aid their antimicrobial effect. The antimicrobial effects of the nanoparticle solutions continued as the same even after 72 hours of acetic acid treatment. Thus, they were presented as the effective antimicrobial solutions against nosocomial or food-borne pathogenic bacteria.

Although all the results of this study pointed out the important consequences of the phenolic acid applications, various related studies can be performed as the next steps. Undoubtedly the most important step would be the cytotoxicity studies for both free and nanoparticle forms of the phenolic acids. The two important concepts in antimicrobial agent development are the high antimicrobial effect on the pathogens as well as the low damage to eukaryotic cells. Hence, the cytotoxicity test such as MTT may be performed to determine the nontoxic concentrations of the phenolic acids and phenolic acid loaded nanoparticle solutions *in vitro* as well as the animal experimentation to determine their effects *in vivo*. Since our study presented the high antimicrobial effects of the phenolic acids with dose-dependency, the upcoming studies showing the useful doses without a toxic effect *in vitro* and *in vivo* would be highly supportive for phenolic acids/nanoparticles to be presented as promising antimicrobial agents. Besides that, additional studies can be performed to optimize the treatment time and concentration of acetic acid before the nanoparticle application as well as testing their effects more than after 72 hours. The shelf-life of the nanoparticles can be performed by periodically repeating the characterization and antimicrobial studies.

The proteomic study indicated various proteins functioned in the important metabolic pathways. However, these results can be supported via with other -omics studies. Especially the transcriptomic studies such as next generation sequencing may aid proteomics studies in the enlightening the mode of action of antimicrobial agents. The transcript profile of the same bacteria grown under the same conditions can be useful to determine the overlapped genes as targets of the antimicrobial agents. Additionally, the specific mutant strains of the targetted genes can be generated and tested under phenolic acid stresses to determine the exact function of these genes for enlightening the action mechanism of the tested compound. Although the usage of overlapped genes in –omics studies will give more precise results, the proteomics or transcriptomics results can also be used individually with the validation of gene expression changes with RT-qPCR. Since the phenolic acid loaded nanoparticles resulted in the notable antimicrobial effects, the similar mode of action studies including proteomic, transcriptomics and testing mutant strains can also be performed to investigate the action mechanism of nanoparticles. The phenolic acids and nanoparticles loaded with phenolic acids were shown to display a strain-dependent antimicrobial effect in our study. Hence, these agents can be tested on other bacteria at the proteomic and transcriptomic level to be able to compare and point out the strain-dependent nature of these agents.

Our study can be accepted as the first step in the enlightening of phenolic acids action mechanism as well as their usage either in free or nanoparticle forms. To the best of our knowledge, the studies of the antimicrobial effects of phenolic acids at the molecular level is very limited. Hence, our results can be elucidated as the starting points of further studies for investigating the phenolic acids as new antimicrobial agents.

## APPENDIX A

### THE GROWTH CURVE OF *P. aeruginosa*

The growth curve of *P. aeruginosa* was plotted as optical density versus time by measurement of optical density (O.D.) of bacteria spectrophotometrically at 600 nm. The intervals of measurement points were 3 hours during 24 hours of growth in MHB at 37°C. In addition, for viable cell count, colony forming unit per milliliters (cfu/ml) were calculated by counting the colonies on agar plates which were inoculated by spread plating at least 3 hours of intervals for 24 hours. According to results of spectrophotometric measurements the bacteria displayed the growth curve which fit the general curve of bacterial growth with specific exponential and stationary phases. Figure A.1 demonstrates that the exponential phase of *P. aeruginosa* starts at about 18th hour of growth. *P. aeruginosa* culture starts to have a blue color and the cells start to make clumps by sticking to each other in test tubes from the 15th hour of growth. During the experiments, these clumps were achieved to be destroyed via vortex. However, at the 24th of its growth, the clumps were more adherent and difficult to be destroyed. These cell clumps might cause the O.D. of the *P. aeruginosa* at 24th hour of growth seemed a little more than that of 18th hour in the graph.

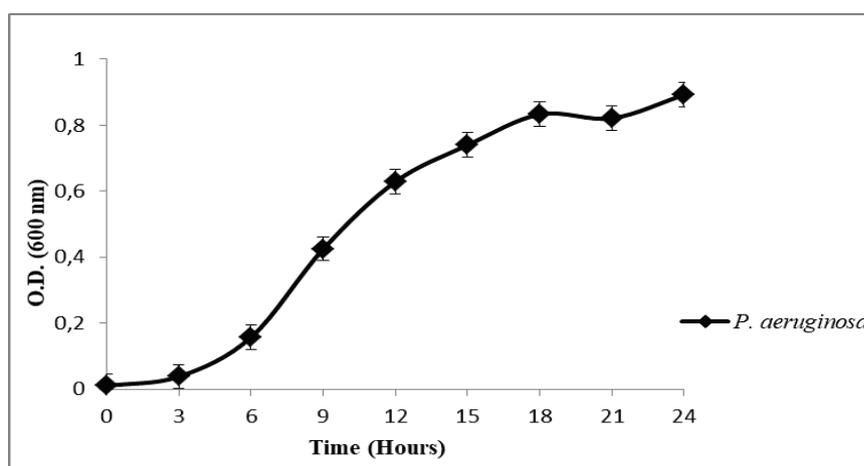

Figure A.1. The growth curve of *P. aeruginosa*.

## APPENDIX B

### THE ANTIMICROBIAL EFFECTS OF A NARROW RANGE OF CONCENTRATIONS

The antimicrobial effects of 3-HPAA and 4-HBA were tested on *P. aeruginosa* in a narrow range of concentrations. These additional experiments were performed by the same technique used in Chapter 2 with a different brand of media. In the main antimicrobial and protein experiments in Chapter 2 and 3, Mueller Hinton Media with Fluka Brand were used. Since Fluka MHB media was consumed in all previous experiments, the same media with Sigma brand was thought to be proper (Sigma-Aldrich was incorporated Fluka brand). Surprisingly, different MIC and MBC values were obtained than these values of previous experiments when the different brand media were used.

In the experiments which were carried out with with Fluka brand MHB, 1.9 mg/ml 3-HPAA showed 58% inhibition on *P. aeruginosa* (Table 2.1.) was chosen for using in shot-gun proteomics as a subinhibitory concentration. When the experiments were performed with Sigma brand MHB, the percent inhibition of 1.9 mg/ml 3-HPAA was found as 25%. Although it is still a subinhibitory concentration, the percent inhibition was found as decreased about half of the previous experiments. The MIC was determined as 2.1 mg/ml and 2.3 mg/ml for 3-HPAA in the experiments carried out with Fluka and Sigma, respectively.

In the case of 4-HBA, 1.5 mg/ml had 39% inhibition and 1.7 mg/ml had 71% inhibition in the previous experiments (Table 2.1.). Thus, 1.6 mg/ml was used for shot-gun proteomics experiments since it would show a percent inhibition between 39-71%. In addition, MIC was found as 1.9 mg/ml (Table 2.1.). However in the experiments performed by Sigma brand MHB, 1.6 mg/ml showed a 12% inhibition and the MIC was found as 2.0 mg/ml.

Therefore; it could be concluded that the bacteria might behave differently against different brands of broth media. The brand of the media should be considered as an important parameter for obtaining consistent results and brand of media with the same brand should be used during the experiments.

Table B.1. Inhibition of percentages of 3-HPAA and cfu/ml of *P. aeruginosa* of narrow range concentrations.

3-HPAA			4-HBA	
Phenolic acid Concentrations (mg/ml)	Percent Inhibition	Cell Survival	Percentage of Inhibition	Cell Survival
1.5	-1	ND*	4	ND
1.6	2	ND	12	4x10 <sup>8</sup> cfu/ml
1.7	3	ND	40	ND
1.8	21	ND	46	ND
1.9	25	5x 10 <sup>8</sup> cfu/ml	55	ND
2.0	42	ND	98	TMTC
2.1	51	ND	98	TMTC
2.2	65	ND	99	TMTC
2.3	98	TMTC**	99	TMTC
2.4	98	TMTC	98	TMTC
2.5	98	TMTC	98	5x10 <sup>2</sup> cfu/ml
2.6	98	TMTC	98	1x10 <sup>1</sup> cfu/ml
2.7	98	TMTC	98	No survivors
2.8	98	No survivors	98	No survivors
2.9	98	No survivors	99	No survivors
3.0	98	No survivors	98	No survivors

\*ND: Not determined.

\*\*TMTC: Too many to count

## APPENDIX C

### BOVINE SERUM ALBUMIN STANDART CURVE

Since the proteins were dissolved in resuspension buffer for the LC-ESI-MS/MS studies, , Bovine serum albumin (BSA) was also dissolved in resuspension buffer 50-250  $\mu\text{g/ml}$  concentrations. The absorbance values of BSA solutions were measured at 595 nm.

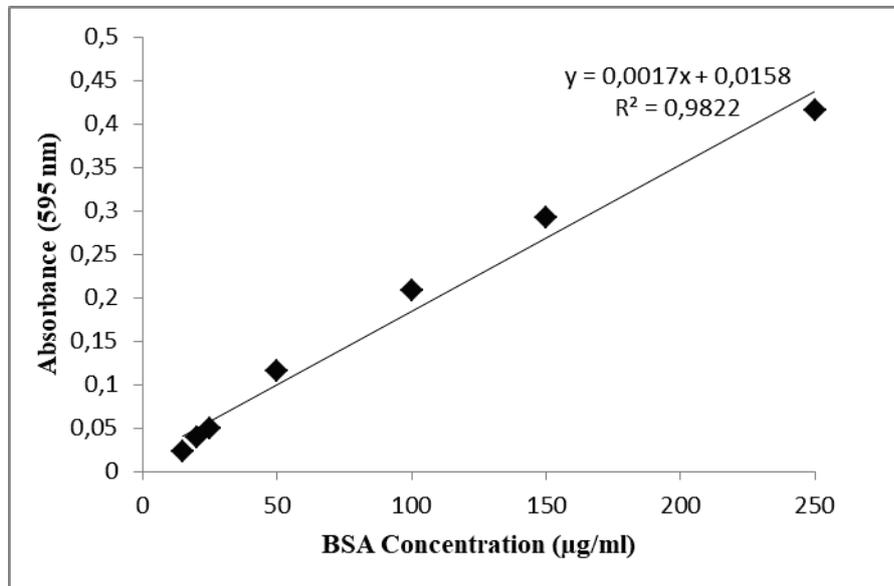

Figure C.1. The standart curve of bovine serum albumin.

## APPENDIX D

### MUTUAL PROTEINS

The mutual proteins which did not change either in control group or phenolic acid treated groups were shown in Table D.1.

Table D.1. Mutual proteins that did not change in *P. aeruginosa* protein profile.

<b>ID</b>	<b>Protein Name</b>	<b>Gene Name</b>
P48372	DNA gyrase subunit A	gyrA PA3168
P28811	3-hydroxyisobutyrate dehydrogenase	mmsB PA3569
O52760	DNA-directed RNA polymerase subunit alpha	rpoA PA4238
Q9HUC3	Polyhydroxyalkanoate synthesis protein PhaF	phaF PA5060
P13982	Carbamate kinase	arcC PA5173
Q9HVC5	Ribose-phosphate pyrophosphokinase	prs PA4670
Q9HZP5	Electron transfer flavoprotein-ubiquinone oxidoreductase	PA2953
Q59637	Pyruvate dehydrogenase E1 component	aceE aceA, PA5015
Q9I2W7	Putative 4-hydroxy-4-methyl-2-oxoglutarate aldolase	PA1772
Q9HY22	Response regulator ErdR	erdR PA3604
Q9HTD1	Probable transcarboxylase subunit	PA5435
Q9HW32	Insulin-cleaving metalloproteinase outer membrane protein	icmP PA4370
Q9I576	4-hydroxyphenylpyruvate dioxygenase	hpd PA0865
Q9HYX8	Peptidyl-prolyl cis-trans isomerase	PA3262
Q9HZH7	Molybdenum cofactor biosynthesis protein B	moaB2 PA3029
Q9I659	Probable ClpA/B protease ATP bindin...	PA0459
Q9I5E2	2-methylisocitrate lyase	prpB PA0796
Q9HYZ6	Site-determining protein	minD PA3244
P50987	Argininosuccinate lyase	argH PA5263
Q9I0A0	Translation initiation factor IF-3	infC PA2743
Q9I2V5	Aconitate hydratase B	acnB PA1787
O50175	N-succinylarginine dihydrolase	astB aruB, PA0899
P72173	Aspartate aminotransferase	aspC PA3139

(cont. on next page)

Table D.1. (continued)

Q9HXN2	Phosphoribosylformylglycinamide synthase	purL PA3763
Q9I1M0	Lipoamide acyltransferase component of branched-chain alpha-keto acid dehydrogenase complex	bkdB PA2249
Q9I0K4	Isocitrate lyase	PA2634
Q9I6M4	5-aminovalerate aminotransferase DavT	davT PA0266
P47205	UDP-3-O-acyl-N-acetylglucosamine deacetylase	lpxC envA, PA4406
Q9HTM1	DNA-directed RNA polymerase subunit omega	rpoZ PA5337
Q9I6J1	Putrescine-binding periplasmic protein SpuD	spuD PA0300
Q9HZJ5	DNA topoisomerase 1	topA PA3011
Q9I3D3	2-oxoglutarate dehydrogenase (E1 subunit)	sucA PA1585
Q9HX05	Probable aldehyde dehydrogenase	PA4022
Q59636	Nucleoside diphosphate kinase	ndk PA3807
Q9I4X2	2-heptyl-4(1H)-quinolone synthase subunit PqsB	pqsB PA0997
Q9I747	Protein hcp1	hcp1 PA0085
Q9HTR6	Nitrogen regulatory protein P-II 2	glnK PA5288
Q9I5Y4	Phosphoglycerate kinase	pgk PA0552
Q9I636	Malate synthase G	glcB PA0482
Q9HW68	Fumarate hydratase class I	PA4333
Q9HZK4	Glyceraldehyde-3-phosphate dehydrogenase	PA3001
P13794	Outer membrane porin F	oprF PA1777
Q9I6Z3	Alkyl hydroperoxide reductase subunit C	ahpC PA0139
Q51404	Fumarate hydratase class II 2	fumC2 PA4470
Q9HVA8	Ferric iron-binding periplasmic protein HitA	hitA PA4687
Q9HVN5	Chaperone protein ClpB	clpB PA4542
Q9HUY5	Mg(2+) transport ATPase, P-type 2	mgtA PA4825
Q9I047	Transaldolase	tal PA2796
Q9I2W9	Phosphoenolpyruvate synthase	ppsA PA1770
Q9HTP2	Probable aldehyde dehydrogenase	PA5312
Q9HVT7	Aspartyl/glutamyl-tRNA(Asn/Gln) amidotransferase subunit B	gatB PA4484
Q9I344	Chorismate synthase	aroC PA1681
Q9HXJ4	4-hydroxy-3-methylbut-2-en-1-yl diphosphate synthase (flavodoxin)	ispG PA3803
Q9HW04	Arginine biosynthesis bifunctional protein ArgJ	argJ PA4402
P57112	Soluble pyridine nucleotide transhydrogenase	sthA sth, PA2991
Q9HV55	Translation initiation factor IF-2	infB PA4744
Q9I4W0	Phosphoribosylaminoimidazole-succinocarboxamide synthase	purC PA1013

(cont. on next page)

Table D.1. (continued)

Q9I5I4	Probable enoyl-CoA hydratase/isomerase	PA0745
Q9HZ98	Heat-shock protein IbpA	ibpA PA3126
Q9HT17	ATP synthase subunit delta	atpH PA5557
Q9I5Z0	S-adenosylmethionine synthase	metK PA0546
Q9HZE0	NAD-specific glutamate dehydrogenase	gdhB PA3068
Q9I5E4	Probable aconitate hydratase	PA0794
P08308	Ornithine carbamoyltransferase, catabolic	arcB PA5172
Q9HWD2	Elongation factor G 1	fusA fusA1, PA4266
Q9HUD3	Malic enzyme	PA5046
Q9HT21	ATP synthase epsilon chain	atpC PA5553
Q9HZP7	Electron transfer flavoprotein subunit alpha	etfA PA2951
Q9HZJ2	Fatty acid oxidation complex subunit alpha	fadB PA3014
Q9I4I2	Ribonucleoside-diphosphate reductase subunit beta	nrdB PA1155
P05384	DNA-binding protein HU-beta	hupB PA1804
Q9HV43	Chaperone protein DnaK	dnaK PA4761
Q9HZF5	Probable hydrolytic enzyme	PA3053
Q9I3D2	Dihydropolyllysine-residue succinyltransferase component of 2-oxoglutarate dehydrogenase complex	sucB PA1586
P53641	Superoxide dismutase [Fe]	sodB PA4366
Q9HWW7	Probable thioredoxin	PA4061
Q9HT16	ATP synthase subunit b	atpF PA5558
Q9I2U0	ATP-dependent Clp protease ATP-binding subunit ClpX	clpX PA1802
Q9I4Z4	Peptidoglycan-associated lipoprotein	pal oprL, PA0973
Q51344	Aspartate-semialdehyde dehydrogenase	asd PA3117
P57668	Thiol peroxidase	tpx PA2532
Q59638	Dihydropolyllysine-residue acetyltransferase component of pyruvate dehydrogenase complex	aceF aceB, PA5016
Q9HX76	Probable DNA binding protein	PA3940
Q9HV54	Transcription termination/antitermination protein NusA	nusA PA4745
Q9HXV4	Adenylate kinase	adk PA3686
Q9HW45	Xenobiotic reductase	xenB PA4356
Q9I0J6	NADH-quinone oxidoreductase subunit G	nuoG PA2642
Q9X2T1	Thioredoxin	trxA trx, PA5240
O30508	Succinylornithine transaminase/acetylornithine aminotransferase	aruC argD, astC, PA0895
P28810	Methylmalonate-semialdehyde dehydrogenase [acylating]	mmsA PA3570
Q9HU24	dTDP-glucose 4,6-dehydratase	rmlB PA5161

## APPENDIX E

### THE ANTIMICROBIAL EFFECTS OF THE CONCENTRATIONS OF PHENOLIC ACIDS USED IN NANOPARTICLE PRODUCTION

The concentrations of phenolic acids which were used in nanoparticle production demonstrated bacteriocidal effect on *P. aeruginosa* (Figure E.1; Table E.1)

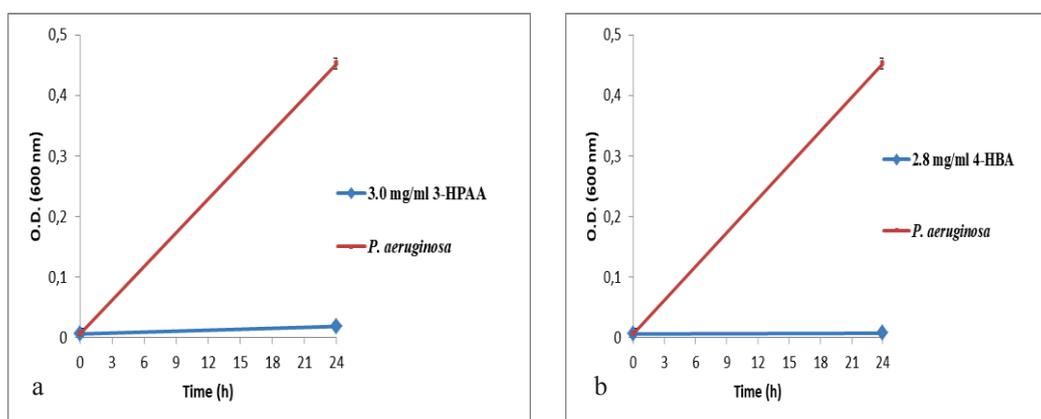

Figure E.1. The antimicrobial effect of concentrations which were used in nanoparticle production on *P. aeruginosa*. a) 3-HPAA b) 4-HBA

Table E.1. The effect of the phenolic acid concentrations used in nanoparticle production in terms of percent inhibition and cell survival.

Phenolic Acid Concentration	Percentage of Inhibition	Cell Survival
3-HPAA (3.0 mg/ml)	96	No survivors
4-HBA (2.8 mg/ml)	98	No survivors

## APPENDIX F

### THE EFFECT OF ETHANOL CONCENTRATIONS ON *Staphylococci*

Since 70% ethanol did not present inhibition zones for *S. epidermidis*, MRSA and MSSA in agar diffusion studies with nanoparticle solutions, the concentration range of ethanol was tested on *Staphylococci* and compared with inhibition of household bleach (Figure F.1.-a,b,c).

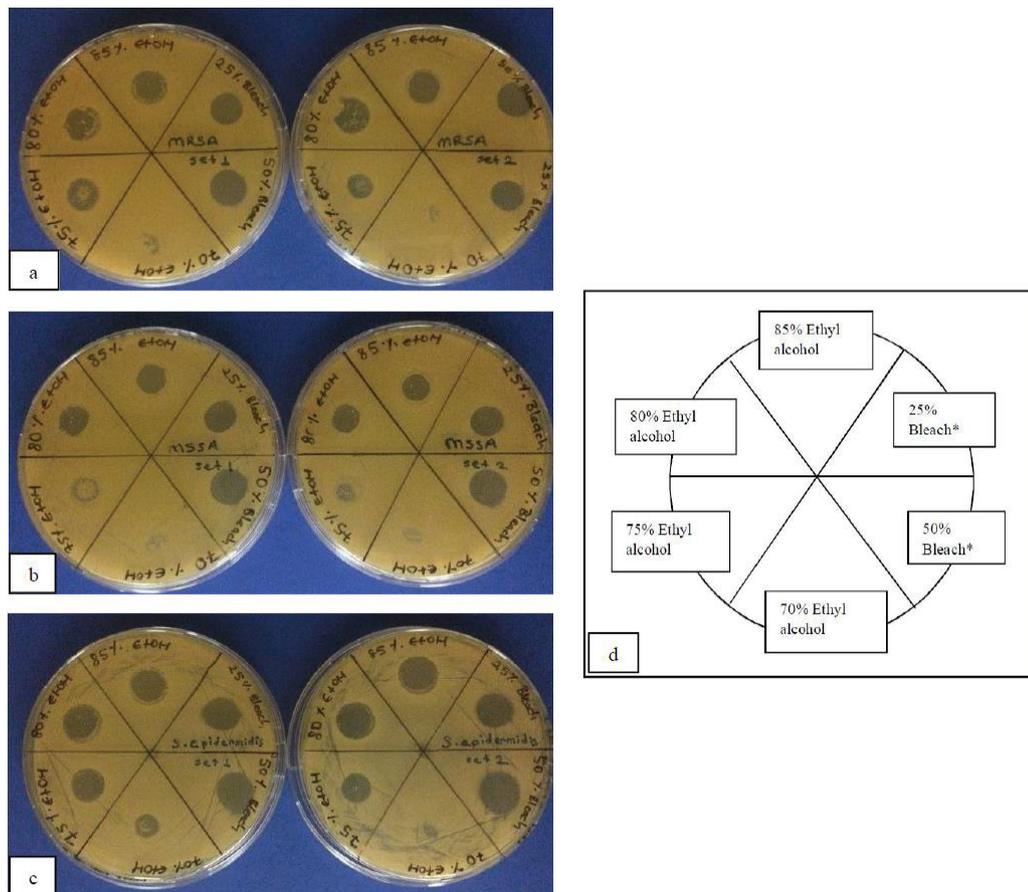

Figure F.1. The effect of ethanol on *Staphylococci*. Different sets (Set 1: left; Set 2: right) of the same bacteria; a) MRSA b) MSSA c) *S. epidermidis* d) The template which shows the regions of the solutions on agar plates

The solutions in agar plates has an exception in the template: The locations of 25% and 50% bleach are vice versa in MRSA Set 2 plate (Figure F.1.-d)

The results demonstrated that 70% ethanol caused a new growth on its own inhibition zone for each tested bacteria. The zone was full covered with bacteria in the cases of MRSA and MSSA while a ring-like growth pattern was determined for *S. epidermidis* on the inhibition zone of 70% ethanol. The concentrations of 80% and 85% showed clear inhibition zones similar to 25% household bleach had displayed for each tested bacterium. Therefore, it could be suggested that using ethanol in 80-85% rather than 70% would be much effective on pathogenic *Staphylococci* which are accepted as one of the main agents of many nosocomial infections.

# VITA

## **Date/Place of Birth**

12.01.1986/Ankara, Turkey

## **Educational Background**

Undergraduate: Hacettepe University, Faculty of Science, Department of Biology (2004-2008)

Master of Science: İzmir Institute of Technology, Institute of Engineering and Science, Department of Molecular Biology and Genetics (2009 – 2012)

## **Publications**

1. Telli, Nihat; Güner, Ahmet; Soyer Dönmez, Ferda; Özdemir, Özgün Öykü, Detection of the contamination sources of *Listeria monocytogenes* in pickled white cheese production process line and genotyping with the pulsed-field gel electrophoresis method, 2016, Turk J Vet Anim Sci, doi:10.3906/vet-1511-59.
