# INVESTIGATION OF COMPRESSOR CYCLE OPERATING POINT FOR VARIOUS AIR CONDITIONS 

A Thesis Submitted to the Graduate School of Engineering and Science of İzmir Institute of Technology in Partial Fulfillment of the Requirements for the Degree of<br>MASTER OF SCIENCE<br>in Mechanical Engineering<br>by<br>Soykan YAȘAR

October 2019
IZMİR

We approve the thesis of Soykan YAŞAR

## Examining Committee Members:

Assoc. Prof. Dr. Erdal ÇETKİN<br>Department of Mechanical Engineering, İzmir Institute of Technology

## Prof. Dr. Tahsin BAŞARAN

Department of Architecture, İzmir Institute of Technology

## Prof. Dr. Aytunç EREK

Department of Mechanical Engineering, Dokuz Eylül University

7 October 2019

Assoc. Prof. Dr. Erdal ÇETKİN<br>Supervisor, Department of Mechanical<br>Engineering, İzmir Institute of<br>Technology

Head of the Department of Mechanical Engineering

## ACKNOWLEDGMENTS

First of all, I would like to express my appreciation to my advisor Dr. Erdal ÇETKİN, for his guidance and help throughout this thesis.

I also would like to thank, I take this opportunity to express my gratitude to my family, Filiz, Serkan and Hikmet YASAR. They stood by me in every decision I made, gave me courage to step up, help me become the person I am.

Last but not least, I would like to thank my prospective partner, Gizem OZARKALIOGLU for her endless care, love and support.

#### Abstract

\section*{INVESTIGATION OF COMPRESSOR CYCLE OPERATING POINT FOR VARIOUS AIR CONDITIONS}

In this study, operating point of compression cycle for various conditions is documented with the consideration of all the equipment of vapor-compression refrigeration cycle. An algorithm which characterizes all the equipment, simulation of the cycle and enabling of the calculation of capacitive values is proposed. The algorithm includes compressor capacitive value polynomial coefficients, air and refrigerant side pressure drop and heat transfer correlations (for finned heat exchangers) which were taken from the literature to uncover the operating point and performance of each equipment in the cycle. e-Ntu and LMTD relations are discussed and proper correlations are included on the thesis. Furthermore, the mathematical models in the literature were surveyed in order to uncover circuiting analysis performed in the cycles.

Keywords and Phrases: HVAC, Compressor Cycle, Refrigeration, Heat exchanger

## ÖZET

## ÇEŞiTLİ HAVA KOŞULLARINDA KOMPRESÖR ÇEVİRİMİ ÇALIŞMA NOKTASININ ARAŞTIRILMASI

Bu çalışmada, buhar sıkıştırmalı kompresör çevrimi çalışma noktası, buhar sıkıştırmalı soğutma çevrimi ekipmanlarını kapsayacak şekilde incelenmiştir. İncelenen bu ekipmanların kapasitif hesaplamaların yapılabilmesi ve kompresör çevrimin similasyonunun gerçekleştirilebilmesi için algoritma mantığı araştırılmıştır. Kompresör kapasite hesaplarında polinom katsayıları, eşanjör yapılarında finli borulu eşanjörlerin hava ve akışkan tarafı isı transfer ve basınç kaybı korelasyonları literatürden bulunmuştur. Isı transfer hesaplamaları için e-Ntu ve LMTD metodları üzerinde çalışılmış ve uygun korelasyonlar listelenmiştir. Bunun yanı sıra finli borulu eşanjörlerde matematiksel modeller, farklı devreleme şekillerine yönelik çevrim analizlerini gerçekleştirebilmek için irdelenmiştir.

Anahtar Kelimeler ve İfadeler: HVAC, Kompresör çevrimi, Soğutma, Isı değiştirgeci

## TABLE OF CONTENTS

CHAPTER 1 INTRODUCTION ..... 1
1.1 AIR CONDITIONING DESIGN METHODOLOGY ..... 1
1.2 HEAT EXCHANGER TYPES IN COMPRESSOR CYCLE ..... 3
1.2.1 Finned Tube Heat Exchanger ..... 3
1.2.2 Microchannel heat exchangers ..... 3
1.2.3 Shell \& tube heat exchangers ..... 4
1.2.4 Plate heat exchangers ..... 4
1.3 COMPRESSOR TYPES ..... 6
1.4 OTHER EQUIPMENT ..... 7

## CHAPTER 1

## INTRODUCTION

Air conditioning/refrigeration with vapor-compression cycle was commercialized in 1911. This commercializing was enabled advancement in distinct fields from air conditioning to transportation of foods. Therefore, cooling with vapor compression cycle became a necessity for everyone. Here we focus on the vapor compression cycle specifically used for space cooling applications such as household and office air conditioning, cold room units and data center cooling. These systems are the most common ones.

Generally, two working fluids (air and water) are being used in air conditioning applications. The energy of the working fluid is transferred to the coolant at the evaporator. Then it is discharged to the ambient at the condenser. Here, we benefit from the current heat exchanger designs and their heat transfer calculations in the literature and also from the compressor correlations in order to investigate how the compressor cycle can be simulated in various air conditioning applications.

There are many distinct evaporator and condenser designs both on the market and in the literature; however, heat pump vapor compression cycle simulation software is very rare, i.e. only 3: EvapCond [1], ACHP [2], RooftopSelector [3]. The market and literature require a simulation program which simulates the effect of all the components in the refrigeration cycle instantly due to several reasons. First, designers generally use a specific program for heat exchanger design and another for selecting compressor. In order to assure the most appropriate equipment selection, iterative calculation method is essential. In addition, the current approach pressure equalization is overlooked as a result of which causes a lot of problems on the field.

### 1.1 AIR CONDITIONING DESIGN METHODOLOGY

A typical air conditioner system has four main components: compressor, condenser,
expansion valve and evaporator. Another essential component in the vapor compression cycle is the type of the refrigerant, because it changes the entire characteristics of the cycle.

Therefore, it is a never-ending process for new refrigerants to be developed for many distinct applications. Currently developed refrigerants have relatively decreased effects on the environment in comparison to their predecessors. Until very recently R410a and R134a refrigerants were common, but nowadays R32 and R1234yf refrigerants are being used on the market. Furthermore, with the new regulations such as ERP 2018 and ERP 2021, the expected seasonal efficiency values are being increased for the commercial units.

Due to the expectations of the market and regulations, the effect of the refrigerants on the environment is going to be decreasing. Nowadays, refrigerants are released to the market according to their GWP (Global warming potential). Old and new refrigerant GWP and Ozone Depletion Potential (ODP) values are listed in the Table1.1.

Table 1-1 Refreigerant's GWP and ODP (Source:[4])

|  | Refrigerant | OWP | GWP |
| :---: | :---: | :---: | :---: |
| Old | R22 | 0,055 | 1810 |
| Old | R410A | 0 | 2088 |
| Old | R134A | 0 | 1430 |
| New | R32 | 0 | 675 |
| New | R1324yf | 0 | 4 |

In addition to the developments related with the refrigerants, the developments on the other equipment are also being continued. For instance; frequency inverter compressors are taking place of on/off compressors, microchannel heat exchangers are preferred to finned tube heat exchangers. However, due to the microchannel evaporator refrigerant distribution problems, it is generally used as condenser in heat pump systems.

Finned tube heat exchanger simulation models have been developed since 1980s, and many researchers have studied the mathematical model of simulations and empirical heat transfer equations. While tube by tube and segment by segment methods have been developed for circuit arrangement [5] [6] [7], refrigerant and air side heat transfer coefficient correlation studies also have been done according to these methods. Furthermore, Domanski et al. managed to programme ISHED which can learn circuit analyze logic. [8]

### 1.2 HEAT EXCHANGER TYPES IN COMPRESSOR CYCLE

On the market, compressor cycle commercial units appear in two categories; air and water cooled. As well as the air finned tube and microchannel heat exchangers, the water plate and shell \& tube heat exchangers are used for cooling and heating.

### 1.2.1 Finned Tube Heat Exchanger

Finned tube heat exchangers are being used for heating and cooling the air on the market. They are not only being used in compressor cycle, but also can condition the air with steam and water. Table 1.2 lists in which applications finned tubes can be used.

Table 1-2 Heat exchanger and flow types

| Type | Primary <br> flow | Secondry <br> flow |
| :---: | :---: | :---: |
| Evaporator | Air/water | Refrigerant |
| Condenser | Air/water | Refrigerant |
| Water cylce heat exc. | Air/water | Water |
| Steam cycle heat exc. | Air/water | Steam |

Figure 1-1 Visual of finned tube heat exchanger (Source: [9])

On finned tube heat exchangers, various fin types such as wavy, plain, louver, slit, are used for increasing the heat transfer between air and the refrigerant. Also grooved or smooth type copper tubes are used for the refrigerant side.

### 1.2.2 Microchannel heat exchangers

The applications in which microchannel heat exchangers are used similar to finned tube heat exchangers, i.e. heating/cooling applications. Although these type of heat exchangers are small (small volume for the same or greater heat transfer surface area) and need less refrigerants for the same capacity range compared to finned tube heat exchangers, they are not preferred due to non-uniform refrigerant distribution problem.

Figure 1-2 Microchannel heat exchanger (Source: [10])

### 1.2.3 Shell \& tube heat exchangers

Shell \& tube heat exchangers are being used in many distinct applications. For specifically cooling applications, they are preferred for conditioning the water in the compressor cycle. Shell \& tube designs are usually used with $5^{\circ} \mathrm{C}$ water temperature difference to assure desired heat transfer. While they require more refrigerant than other heat exchangers, they are preferred due to their high capacity.

### 1.2.4 Plate heat exchangers

The applications in which plate heat exchangers are preferred are the same with the Shell \& tube heat exchangers. There are gasket and brazed type heat exchangers. Gasket plate heat exchangers can be repaired on blockage problems, and its surface area can be increased because they can be disintegrated and montaged with changes. However, brazed types cannot
be disintegrated (brazing connects all the parts similar to they are welded), therefore, brazed types should be replaced when repair is required.

Figure 1-3 Shell \& tube heat exchanger (Source: [11])

Figure 1-4 Gasket plate exchangers (Source: [12])

Figure 1-5 Plate heat exchangers (Source: [13])

### 1.3 COMPRESSOR TYPES

There are three main types of compressors which are, piston, scroll and screw. Although scroll and screw types are taking place of piston compressor. The fact that piston compressors are repairable makes them preferable in the market. The most important difference between screw and scroll types is their capacity range. While scroll compressors are up to 100 kw capacity range screw compressor can reach 500kw cooling capacity [14] [15]. Furthermore, because frequency inverter adaption can be applied to this type of compressors, they provide advantages of energy efficiency and power consumption for the consumers.

Figure 1-6 1-Semi hermetic piston compressor (Source: [16]) 2-Scroll compressor (Source: [17]) 3-Screw compressor (Source: [18])

### 1.4 OTHER EQUIPMENT

Compressor cycle also consists some auxiliary equipment that help the system work properly such as filter dryer, liquid receiver, suction accumulator, ball valve etc. Auxiliary equipment calculations are not examined in this study. Their brief explanation can be found below.

Filter dryer: Filter dryer is used for filtering and dehumidifying the refrigerant in the cycle. Bi-flow and non-return types are on the market.

Liquid receiver: Liquid receiver is used for balancing the refrigerant mass in the system, that the condenser and evaporator are not compact in a unit.

Suction accumulator: This equipment is used for protecting the unit by eliminating return of liquid to compressor.

Ball valve: Ball valve is used for closing the liquid line while fixing the units.

Figure 1-7 Filter dryer (Source: [19])

Figure 1-8 Liquid receiver (Source: [20])

Figure 1-9 Suction accumulator (Source: [21]), Ball valve (Source: [22])

## CHAPTER 2

## COMPONENT MODEL DEVELOPMENT

There are four major components in a typical HVAC system: compressor, condenser, expansion device and evaporator. Compressor compresses the superheated refrigerant from low pressure to high pressure via rotary or reciprocating motion supplied from work input. The refrigerant in the evaporator evaporates while receiving heat from its surrounding. Therefore, evaporators are used for cooling applications. Similarly, phase change occurs in condensers, and therefore heat is transferred from the refrigerant to the environment in condensers. Furthermore, expansion devices are used to decrease the pressure of sub-cooled high pressure refrigerant to low pressure while the expansion process occur at constant enthalpy.

Figure 2-1 Compressor cycle schematic

### 2.5 Calculation Methods of Compressor Cycle Main Equipment

### 2.5.1 Compressor calculations

In HVAC, scroll and reciprocating compressor types are commonly used. Most common performance calculation is rating standart of ARI model [23], which includes the polynomial coefficients of suction and discharge saturation temperatures of compressors. Each coefficient in formula is valid for the specific rating conditions. So, compressor manufacturers are publishing Ci and Di coefficients to calculate the refrigeration capacity, power input, mass flow and current of a specific compressor.

$$
\begin{gather*}
X=C 1+C 2 t_{s}+C 3 t_{d}+C 4 t_{s}^{2}+C 5 t_{s} t_{d}+C 6 t_{d}^{2}+C 7 t_{s}^{3}+C 8 t_{d} t_{s}^{2} \\
+C 9 t_{s} t_{d}{ }^{2}+C 10 t_{d}{ }^{3} \tag{2.1}
\end{gather*}
$$

To be able to calculate the change of capacitive values according to the other superheat values, mass flow should be corrected. [23]. A change of the superheat temperature has a negligible impact on power consumption.

$$
\begin{equation*}
\dot{\mathrm{m}}_{\text {corrected }}=\left\{1+F v\left[\left(v_{\text {rated }} / v_{\text {corrected }}\right)-1\right]\right\} \cdot \dot{\mathrm{m}}_{\text {rated }} \tag{2.2}
\end{equation*}
$$

Besides, subcooling degree can be changed in practical area. So, compressor capacity and COP values should be corrected according to the enthalpy difference.

Figure 2-2 Compressor cycle in PH diagram

$$
\begin{gather*}
Q_{\text {comp,corr }}=\dot{\mathrm{m}}_{\text {corrected }}\left(h_{3}-h_{3 s}\right)  \tag{2.3}\\
\text { COP }{ }_{\text {corr }}=\frac{Q_{\text {comp,corr }}}{Q_{p, i n}} \tag{2.4}
\end{gather*}
$$

### 2.5.2 Finned tube heat exchanger calculations

### 2.5.2.1 Method

Finned tube heat exchanger calculations are differed on three basic calculation method respectively, zone-by-zone, tube-by-tube and segment-by-segment. These methods have advantages to each other. While, tube-by-tube and segment-by-segment models are detailed to analyze heat exchanger circuit design, and proper to use of row-by-row air side heat transfer coefficients, zone-by-zone method does not have these capabilities, however more computationally efficient. In figure 2-3 discretization methods are shown.

Figure 2-3 Heat exchanger calculation models

### 2.5.2.1.1 Zone-by-zone method

Zone by zone calculation method is based on refrigerant position. While, in condenser, there are three zones, named superheated, two phase and subcooled; in evaporator, there are two zones, named two phase and superheated [24]. This calculation method assumes every circuit is the same. Because of that different circuit designs cannot be applied simultaneously.

### 2.5.2.1.2 Tube-by-tube method

Tube-by-tube method assumes that, each single tube is a calculation domain [7]. Because of that, this method allows circuitry algorithm. Inlet and outlet refrigerant properties are constant along the tube. Although this approach requires long computational time, it gives more accurate results than zone-by-zone method. Furthermore, the transition tube can give calculation error because of the constant properties of the refrigerant.

### 2.5.2.1.3 Segment-by-segment method

Segment-by-segment method defines segments in each tube [25]. With this method, transient tube calculation error problem is passed. But, as the segment number increases, computational time increases greatly. Refrigerant properties change after every single segment. Segment by segment calculations can also be adapted to the tube-by-tube calculations by making the segment number 1. Elemental method captures not only the circuitry effect, but also air maldistribution.

### 2.5.2.2 Heat transfer methods

### 2.5.2.2.1 ع-NTU Method

For the calculation of heat exchanger performance, if the inlet temperatures are known, it is preferable to use the effectiveness-number of transfer units ( $\varepsilon$-NTU) method,
which simplifies the algebra involved in predicting the performance of complex flow arrangements. Although $\varepsilon$-NTU Method is the most proper method for the elemental models, because the transition element can be occurred, iteration can give incorrect results. In $\varepsilon$-NTU method, single and two-phase regions should be applied [26].

## Dry conditions

$$
\begin{gather*}
Q=\varepsilon C_{\min }\left(T_{h, i n}-T_{c, \text { in }}\right)  \tag{2.5}\\
N T U=U A / C_{\min } \tag{2.6}
\end{gather*}
$$

Effectiveness can be calculated as follows

For single phase:

If $\mathrm{C}_{\text {min }}$ is unmixed and $\mathrm{C}_{\max }$ is mixed,

$$
\begin{equation*}
\varepsilon_{s p}=\frac{1}{C_{r}}\left(1-\exp \left\{-C_{r}[1-\exp (-N T U)]\right\}\right) \tag{2.7}
\end{equation*}
$$

If $\mathrm{C}_{\text {min }}$ is mixed and $\mathrm{C}_{\text {max }}$ is unmixed,

$$
\begin{equation*}
\varepsilon_{s p}=1-\exp \left\{-\frac{1}{C_{r}}\left[1-\exp \left(-C_{r} N T U\right)\right]\right\} \tag{2.8}
\end{equation*}
$$

If both $\mathrm{C}_{\text {min }}$ and $\mathrm{C}_{\text {max }}$ are unmixed, [27]

$$
\begin{equation*}
\varepsilon_{s p}=1-\exp \left\{-\frac{1}{C_{r}} N T U^{0.22}\left[\exp \left(-C_{r} N T U^{0.78}\right)\right]\right\} \tag{2.9}
\end{equation*}
$$

The unmixed or mixed state of the fluid is determined by the geometry of the fluid flow passages. Flow through a louvered fin heat exchanger is considered mixed since the perforated surface of the louvered fin accommodates cross.mixing of the flow paths. Flow through nonperforated fin heat exchangers is considered unmixed since there is no mechanism for mixing. On the refrigerant side, the refrigerant is always considered unmixed in the
segment-by-segment calculation. The unmixed $C_{\text {min }}$ and $C_{\max }$ equation is more suitable for heat exchangers with smooth fins. Correlations for dry conditions are below. [27]

For two-phase:

$$
\begin{equation*}
\varepsilon_{t p}=1-\exp (-N T U) \tag{2.10}
\end{equation*}
$$

Where

$$
\begin{equation*}
C_{r}=C_{\min } / C_{\max } \tag{2.11}
\end{equation*}
$$

Where $\mathrm{C}_{\text {min }}$ is the minimum value of air and refrigerant heat capacitance, $\mathrm{C}_{\text {max }}$ is the maximum value of air and refrigerant heat capacitance.

$$
\begin{align*}
& C_{a i r}=\dot{\mathrm{m}}_{a i r} c_{p, a i r}  \tag{2.12}\\
& C_{r e f}=\dot{\mathrm{m}}_{r e f} c_{p, r e f} \tag{2.13}
\end{align*}
$$

## Wet conditions

Wet conditions affect heat exchanger effectiveness and heat capacitance ratio calculations. In addition, air side specific heat value is taken at saturation temperature and number of transfer unit calculation logic is the same as the dry surface calculations [5].

$$
\begin{equation*}
Q=\varepsilon_{w e t} \dot{\mathrm{~m}}_{\text {air }}\left(h_{\text {air,in }}-h_{r e f, i n, s a t}\right) \tag{2.14}
\end{equation*}
$$

For single phase:

$$
\begin{gather*}
\dot{\mathrm{m}}_{r e f} c p_{r e f}>\dot{\mathrm{m}}_{\text {air }} c p_{a i r} \\
\varepsilon_{w e t}=\frac{1}{C_{r, w}}\left(1-\exp \left\{-C_{r, w}\left[1-\exp \left(-N T U_{w}\right)\right]\right\}\right) \tag{2.15}
\end{gather*}
$$

$$
\begin{gather*}
\dot{\mathrm{m}}_{r e f} c p_{r e f}<\dot{\mathrm{m}}_{a i r} c p_{a i r} \\
\varepsilon_{w e t}=1-\exp \left\{-\frac{1}{C_{r, w}}\left[1-\exp \left(-C_{r, w} N T U_{w}\right)\right]\right\} \tag{2.16}
\end{gather*}
$$

Where Cr ,w is min value of these both

$$
\frac{\dot{\mathrm{m}}_{r e f} c_{p, r e f}}{\dot{\mathrm{~m}}_{\text {air }} c_{p, \text { sat }}}, \frac{\dot{\mathrm{m}}_{\text {air }} c_{p, \text { sat }}}{\dot{\mathrm{m}}_{r e f} c_{p, r e f}}
$$

Two phase flow:

$$
\begin{gather*}
\varepsilon_{w}=1-\exp \left(-N T U_{w}\right)  \tag{2.17}\\
N T U_{w}=\frac{U A_{w}}{m_{\text {air }}} \tag{2.18}
\end{gather*}
$$

### 2.5.2.2.2 LMTD Method

Log Mean Temperature Difference method is another option to calculate the heat transfer rate. In this method, outlet temperature is needed in order to perform calculations. Hence, if inlet temperatures are known, LMTD method requires iterative procedures. Heat exchanger capacity by using LMTD method can be calculated as follows [26]:

For parallel flow:

$$
\begin{gather*}
Q=U A(L M T D)  \tag{2.19}\\
L M T D=\frac{\Delta T_{2}-\Delta T_{1}}{\ln \left(\Delta T_{2}-\Delta T_{1}\right)}  \tag{2.20}\\
\Delta T_{1}=T_{h, i}-T_{c, i} \tag{2.21}
\end{gather*}
$$

$$
\begin{equation*}
\Delta T_{2}=T_{h, o}-T_{c, o} \tag{2.22}
\end{equation*}
$$

For counter flow:
For counter flow heat exchangers, the correction factor (F) is unity.

$$
\begin{gather*}
Q=U A(L M T D)  \tag{2.23}\\
L M T D=\frac{\Delta T_{2}-\Delta T_{1}}{\ln \left(\Delta T_{2}-\Delta T_{1}\right)}  \tag{2.24}\\
\Delta T_{1}=T_{h, i}-T_{c, o}  \tag{2.25}\\
\Delta T_{2}=T_{h, o}-T_{c, i} \tag{2.26}
\end{gather*}
$$

### 2.5.2.3 Heat transfer equations

In order to calculate overall heat transfer rate of the heat exchanger, thermal circuit model should be considered. In steady state, heat is transferred from the hot fluid to the cold fluid through the wall. During conduction, via tube and fin, the subsequent deposition of a film on the surface can greatly increase the resistance to heat transfer between fluids. Therefore, fouling factor should be considered and inserted to the thermal resistance. While dry condition calculations are as in the traditional heat transfer method, [28] wet surface conditions shown below are modified by Harms et al. [5]

$$
\begin{gather*}
\frac{1}{U A}=\frac{1}{U_{c} A_{c}}=\frac{1}{U_{h} A_{h}}  \tag{2.27}\\
\frac{1}{U A}=\frac{1}{\left(\eta_{o} h A\right)_{c}}+\frac{R_{f, c}{ }^{\prime \prime}}{\left(\eta_{o} A\right)_{c}}+R_{w}+\frac{R_{f, h}^{\prime \prime}}{\left(\eta_{o} A\right)_{h}}+\frac{1}{\left(\eta_{o} h A\right)_{h}} \tag{2.28}
\end{gather*}
$$

If the fouling terms for fin and tube heat exchangers are neglected,

Dry conditions:

$$
\begin{equation*}
\frac{1}{U A}=\frac{1}{h_{\text {ref }} * A_{\text {in }}}+\ln \left(\frac{\left(\frac{D_{o}}{D_{i}}\right)}{2 \pi k_{\text {tube }} L_{\text {tube }}}\right)+\frac{1}{\left(\eta_{\text {surf }} h_{\text {air }} A_{o}\right)} \tag{2.29}
\end{equation*}
$$

Wet conditions:

$$
\begin{equation*}
\frac{1}{U A_{w}}=\frac{c_{p, a i r, s}}{h_{r e f} A_{i n}}+c_{p, a i r, s} \ln \left(\frac{\frac{D_{o}}{D_{i}}}{2 \pi k_{t u b e} L_{t u b e}}\right)+\frac{c_{p, a i r, m}}{\eta_{s u r f, w} h_{a i r} A_{o}} \tag{2.30}
\end{equation*}
$$

Saturation specific heat is calculated as a derivative of saturated air enthalpy at refrigerant temperature:

$$
\begin{equation*}
c_{p, a i r, s}=\frac{d h_{a i r, s}}{d T} \tag{2.31}
\end{equation*}
$$

Where surface and fin efficiencies are calculated according to wet and dry conditions. If the coil surface temperature is below the air saturation temperature, dry and wet surface fin efficiencies are shown below according to the Harms et al. method [5].

$$
\begin{gather*}
\eta_{\text {surf }}=1-\frac{A_{f}}{A_{o}}\left(1-\eta_{f}\right)  \tag{2.32}\\
\eta_{\text {surf }, w}=1-\frac{A_{f}}{A_{o}}\left(1-\eta_{f, w}\right) \tag{2.33}
\end{gather*}
$$

Where fin efficiency;
For dry conditions

$$
\begin{gather*}
\eta_{f}=\frac{\tanh \left(m D_{\text {collar }} \varnothing\right)}{m * D_{\text {collar }} \varnothing}  \tag{2.34}\\
m=\sqrt{\left(\frac{2 h_{\text {air }}}{2 k_{\text {fin }} t_{\text {fin }}}\right)} \tag{2.35}
\end{gather*}
$$

$$
\begin{gather*}
\eta_{f, w}=\frac{\tanh \left(m_{f, w} D_{\text {collar }} \varnothing\right)}{m_{f, w} D_{\text {collar }} \emptyset}  \tag{2.36}\\
m_{f, w}=\sqrt{\left[\frac{2\left(F_{p}+t_{f i n}\right) h_{\text {air }, w} c_{p, a i r, s}}{k_{f} F_{p} t_{f i n} c_{p, a i r}}\right]}  \tag{2.37}\\
d_{\text {collar }}=d_{o}+2 t_{f i n}  \tag{2.38}\\
\emptyset=\left(r_{r}-1\right)\left[1+0,35 \ln \left(r_{r}\right)\right] \tag{2.39}
\end{gather*}
$$

Radius ratio is defined for staggered tubes:

$$
\begin{equation*}
r_{r}=1,27 \frac{X_{m}}{d_{\text {collar }}} \sqrt{\left[\frac{X_{l}}{X_{m}}-0,3\right]} \tag{2.40}
\end{equation*}
$$

Where $\mathrm{X}_{1}$ and $\mathrm{X}_{\mathrm{m}}$ are geometric parameters that are correlated to the tube pitch $\left(\mathrm{P}_{\mathrm{t}}\right)$ and row pitch $\left(\mathrm{P}_{1}\right)$ as follows:

$$
\begin{align*}
& X_{m}=\frac{P_{t}}{2} \text { if } P_{t} \leq P_{l}  \tag{2.41}\\
& X_{m}=P_{l} \text { if } X_{m}>P_{l}  \tag{2.42}\\
& X_{l}=\frac{1}{2} \sqrt{\left(\frac{P_{t}}{2}\right)^{2}+P_{l}^{2}} \tag{2.43}
\end{align*}
$$

Where colar radius is the tube outside radius including fin collar.

In order to decrease calculation time, Braun et all [5] recommends the calculation method mentioned below to find out the air outlet temperature and enthalpy according to wet and dry conditions.

Outlet air conditions for dry conditions

$$
\begin{equation*}
T_{a, \text { out }}=T_{a, \text { in }}+\varepsilon_{a}\left(T_{c, s}-T_{a, \text { in }}\right) \tag{2.44}
\end{equation*}
$$

$$
\begin{gather*}
N T U_{a}=\frac{\eta_{\text {surf }} h_{a i r} A_{o}}{C_{p, a i r}}  \tag{2.45}\\
\varepsilon_{a}=1-e^{-N T U_{a}} \tag{2.46}
\end{gather*}
$$

Outlet air conditions for wet conditions, b33

$$
\begin{gather*}
T_{a, o u t}=T_{a, \text { in }}+\varepsilon_{a}\left(T_{e}-T_{a, \text { in }}\right)  \tag{2.47}\\
h_{a, \text { out }}=h_{a, \text { in }}+\varepsilon_{a}\left(h_{s, c}-h_{a, i n}\right)  \tag{2.48}\\
N T U_{a}=\frac{\eta_{s u r f, w} h_{a i r, w} A_{o}}{C_{p, a i r}}  \tag{2.49}\\
\varepsilon_{a}=1-e^{-N T U_{a}} \tag{2.50}
\end{gather*}
$$

Figure 2-4 Heat transfer ratio electrical analogy

### 2.5.2.4 Junction tube matrix

To simulate air outlet conditions and refrigerant outlet conditions junction tube matrix is being used with segment by segment method. With this method two-dimensional nonuniformity of air distribution can be applied. A change in the single and two-phase segment can be obtained according to segment number arrangement, as well. Moreover, different circuitry algorithms can be applied with this method and most effective heat exchanger capacity solution can be found.

The term 'junction' is defined as the intersection where two or more tubes are joined together [25].The relationships are shown as follows:
$J T A[n, i, j]=1 \quad$ :junction $n$ is upstream and connected to tube at row $i$ column $j$ JTA[n,i,j]=-1 :junction $n$ is downstream and connected to tube at row i column j $\operatorname{JTA}[\mathrm{n}, \mathrm{i}, \mathrm{j}]=0$ : junction n is not connected to tube at row i column j

According to the information in the junction tube connectivity matrix, the following can be determined:

- Refrigerant phase position and pressure drops can be calculated
- Refrigerant mass flow in each circuit can be calculated
- Different working fluids in different circuits can be calculated

In the study of Jiang et al. a sample circuit schema, table and model assumptions are shown below [25]. Each segment is treated as a discrete unit of heat transfer, without considering the conduction of heat transfer through the fin plates between tubes.

When the air flow at the face of the heat exchanger is non-uniform (i.e. different air velocities at different segments of the tubes in the frontal face row), the air velocity at the segments in the air flow direction across the heat exchanger remains the same as that at the corresponding segment in the frontal face. The air side heat transfer coefficient for each segment is calculated based on the individual air velocity at that segment. When dehumidification occurs, the heat transfer resistance due to the water film on the surface of the tube and the fin, is either neglected or can be accounted for by adding a certain value of resistance to the fin-tube contact resistance.

Figure 2-5 Circuit schematic (Source: [25])

Refrigerant pressure drop is calculated in each segment, and in each segment refrigerant properties are constant.

$$
\begin{equation*}
P_{i, j, k, \text { in }}-P_{i, j, k, \text { out }}=\Delta P_{f}+\Delta P_{a}+\Delta P_{g} \tag{2.51}
\end{equation*}
$$

Where;
i: row number
j: column number
k : segment number for refrigerant flow

## $\Delta \mathrm{P}_{\mathrm{f}}$ : Friction term

$\Delta \mathrm{P}_{\mathrm{a}}$ : Acceleration term
$\Delta \mathrm{P}_{\mathrm{g}}$ : Gravitational term
Pressure drop calculation will be detailed in section 2.1.2.6.

For staggered tube arrangement:

$$
\begin{equation*}
\dot{\mathrm{m}}_{a i r, i, j+1, k, \text { in }}=0,5\left(\dot{\mathrm{~m}}_{a i r, i, j, k, o u t}+\dot{\mathrm{m}}_{a i r, i+1, j, k, o u t}\right) \tag{2.52}
\end{equation*}
$$

$$
\begin{align*}
& \dot{\mathrm{m}}_{a i r, i, j+1, k, \text { in }} h_{a i r, i, j+1, k, \text { in }}  \tag{2.53}\\
&=0,5\left(\dot{\mathrm{~m}}_{\text {air }, i, j, k, o u t} h_{a i r, i, o u t}+\dot{\mathrm{m}}_{a i r, i+1, j, k, o u t} h_{a i r, i+1, j, o u t}\right) \\
& \dot{\mathrm{m}}_{\text {air }, i, j+1, k, \text { in }} * w_{\text {air }, i, j+1, k, \text { in }}  \tag{2.54}\\
&=0,5\left(\dot{\mathrm{~m}}_{\text {air }, i, j, k, o u t} w_{a i r, i, o u t}+\dot{\mathrm{m}}_{a i r, i+1, j, k, o u t} w_{a i r, i+1, j, o u t}\right)
\end{align*}
$$

Table 2-1 Junction tube matrix index (Source: [25])

|  |  | Tube (row, column) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1,1 | 1,2 | 1,3 | 1,4 | 2,1 | 2,2 | 2,3 | 2,4 |  |  |
| Junction | 1 | -1 | 1 |  |  |  |  |  |  |  |
|  | 2 |  |  |  |  | -1 | 1 |  |  |  |
|  | 3 |  | -1 | 1 |  |  | -1 |  |  |  |
|  | 4 |  |  | -1 |  |  |  | 1 |  |  |
|  | 5 |  |  |  | 1 |  |  | -1 |  |  |
|  | 6 |  |  |  | -1 |  |  |  | 1 |  |

For inline tube arrangement:

$$
\begin{gather*}
\dot{\mathrm{m}}_{\text {air }, i, j+1, k, i n}=\dot{\mathrm{m}}_{\text {air }, i, j, k, o u t}  \tag{2.55}\\
h_{\text {air }, i, j+1, k, i n}=h_{\text {air }, i, j, k, o u t}  \tag{2.56}\\
w_{\text {air }, i, j+1, k, \text { in }}=w_{\text {air }, i, j, k, o u t} \tag{2.57}
\end{gather*}
$$

### 2.5.2.5 Air side heat transfer and pressure drop correlations

Air side and pressure drop correleations in the litterature are usually according to Colburn j and friction factor. Researchers have made a lot different tests and data reduction methods according to heat exchanger geometries. Although there are studies for wet surface conditions, most common cases are at the dry conditions.

$$
\begin{gather*}
j=\frac{h_{\text {air }}}{G_{a i r, \max } c_{p, \text { air }}} \operatorname{Pr}_{\text {air }}{ }^{2 / 3}  \tag{2.58}\\
f=\frac{A_{c}}{A_{o}} \frac{\rho_{m}}{\rho_{1}}\left[\frac{2 \Delta P \rho_{1}}{G_{c}{ }^{2}}-\left(1+\sigma^{2}\right)\left(\frac{\rho_{1}}{\rho_{2}}-1\right)\right] \tag{2.59}
\end{gather*}
$$

Correlations for plain, wave, louver and slit fins at dry surface conditions are shown below.

### 2.5.2.5.1 Plain fins:

## For dry conditions; [29]

For $\mathrm{N}=1$;

$$
\begin{equation*}
j=0.108 R e_{D c}{ }^{-0.29}\left(\frac{P_{t}}{P_{l}}\right)^{j_{1}}\left(\frac{F_{p}}{D_{C}}\right)^{-1.084}\left(\frac{F_{p}}{D_{h}}\right)^{-0.786}\left(\frac{F_{p}}{P_{t}}\right)^{j_{2}} \tag{2.60}
\end{equation*}
$$

Where

$$
\begin{gather*}
j_{1}=1.9-0.23 \ln \left(R e_{D c}\right)  \tag{2.61}\\
j_{2}=-0.236+0.126 \ln \left(R e_{D c}\right) \tag{2.62}
\end{gather*}
$$

For $\mathrm{N} \geq 2$;

$$
\begin{equation*}
j=0.086 * R e_{D c}{ }^{j_{3}} N^{j_{4}}\left(\frac{F_{p}}{D_{C}}\right)^{j_{5}}\left(\frac{F_{p}}{D_{h}}\right)^{j_{6}}\left(\frac{F_{p}}{P_{t}}\right)^{-0.93} \tag{2.63}
\end{equation*}
$$

Where

$$
\begin{gather*}
j_{3}=-0.361-\frac{0.42 N}{\ln \left(R e_{d c}\right)}+0.158 \ln \left(N\left(\frac{F_{p}}{D_{c}}\right)^{0.41}\right)  \tag{2.64}\\
\mathrm{j}_{4}=-1.224-\frac{0.076\left(\frac{\mathrm{P}_{\mathrm{l}}}{\mathrm{D}_{\mathrm{h}}}\right)^{1.42}}{\ln \left(\mathrm{Re}_{\mathrm{Dc}}\right)}  \tag{2.65}\\
\mathrm{j}_{5}=-0.083+\frac{0.058 \mathrm{~N}}{\ln \left(\mathrm{Re}_{\mathrm{Dc}}\right)}  \tag{2.66}\\
\mathrm{j}_{6}=-5.735+1.21 \ln \left(\frac{\mathrm{Re}_{\mathrm{Dc}}}{\mathrm{~N}}\right)  \tag{2.67}\\
\mathrm{f}=0.0267 \mathrm{Re}_{\mathrm{Dc}}{ }^{\mathrm{F} 1}\left(\frac{\mathrm{P}_{\mathrm{t}}}{\mathrm{P}_{1}}\right)^{\mathrm{F} 2}\left(\frac{\mathrm{~F}_{\mathrm{p}}}{\mathrm{D}_{\mathrm{c}}}\right)^{\mathrm{F} 3}  \tag{2.68}\\
\mathrm{~F}_{1}=-0.764+0.739 \frac{\mathrm{P}_{\mathrm{t}}}{\mathrm{P}_{\mathrm{l}}}+0.177 \frac{\mathrm{~F}_{\mathrm{p}}}{\mathrm{D}_{\mathrm{c}}}-\frac{0.00758}{\mathrm{~N}} \tag{2.69}
\end{gather*}
$$

$$
\begin{gather*}
\mathrm{F}_{2}=-15.689+\frac{64.021}{\ln \left(\mathrm{Re}_{\mathrm{Dc}}\right)}  \tag{2.70}\\

\varepsilon=\frac{A_{o}}{A_{p}} \tag{2.77}
\end{gather*}
$$

In 2007 Pirompugd et al. [31] used finite circular fin method for wet surfaces. In this method, heat exchangers divided into little segments and separated into three main region named respectively, fully dry, fully wet and partially wet. Although Wang and Pirompugd developed their correlations for plain and wave finned heat exchangers, correlations are still for narrow geometry ranges.

(a) Dividing the wavy fin-and-tube heat exchangers into may tiny segments

(b) Equivalent circular area method

(c) Circular fin in fully dry, fully wet and partially wet conditions

Fig. 3. Finite circular fin method (FCFM).

Figure 2.6 Air side fully dry, fully wet and partially wet conditions on the tubes (Source: [32])

For plain fins Pirompugd and Wang [33] published the correlations as added below.
Fully wet conditions: 1, 2, 4, 6 Rows and partially wet conditions 1, 2, 4 Rows

$$
\begin{gather*}
j=a R e_{D c}\left(b \frac{F_{s}}{F_{p}}+c \frac{P_{l}}{D_{c}}+d \frac{P_{t}}{D_{c}} e e\right)  \tag{2.78}\\
\mathrm{j}_{\mathrm{h}, 6, \mathrm{partial}}=\left(738.92534 \frac{\mathrm{~F}_{\mathrm{s}}}{\mathrm{~F}_{\mathrm{p}}{ }^{2}}-1390.12647 \frac{\mathrm{~F}_{\mathrm{s}}}{\mathrm{~F}_{\mathrm{p}}}+654.15084\right)  \tag{2.79}\\

### 2.5.2.6 Refrigerant side heat transfer correlations

In the literature, there are many studies on refrigerant side heat transfer and pressure drop correlations. In this section, correlations will be explained to implement segment by segment method. Correlations are examined according to the refrigerant phase change procedure in horizontal smooth tubes.

Two phase examinations are the most complex part for heat exchanger calculations. While a lot of overall refrigerant heat transfer calculations are enough for tube by tube methods, for segment by segment method, refrigerant phase changing conditions in two phase region are getting more complex.

### 2.5.2.6.1 Two Phase Condensation

Thome et al. [40] developed a new flow pattern map for refrigerant condensation in horizontal tubes. According to this method, new regions are introduced for refrigerant flow name, fully-stratified (S), stratified wavy (SW), intermittent (I), annular (A), mist (MF) and bubbly(B) flow. Thome et al. calculated transition mass flow velocities for each region to decide the flow regimes. Ranges for flow pattern is shown below.
Annular flow
$\mathrm{G}>\mathrm{G}_{\text {wavy }}, \mathrm{G}<\mathrm{G}_{\text {mist }}$ or $\mathrm{G}<\mathrm{G}_{\text {bubbly }}$ and $\mathrm{x}<\mathrm{x}_{\text {IA }}$
Intermittent flow
$\mathrm{G}>\mathrm{G}_{\text {wavy }}, \mathrm{G}<\mathrm{G}_{\text {mist }}$ and $\mathrm{x}>\mathrm{x}_{\text {lA }}$
Stratified wavy flow
$\mathrm{G}_{\text {strat }}<\mathrm{G}<\mathrm{G}_{\text {wavy }}$
Fully stratified flow
$\mathrm{G}<\mathrm{G}_{\text {strat }}$
Mist flow
$\mathrm{G}>\mathrm{G}_{\text {mist }}$
Calculations are given below respect to the calculation order.

\end{gather*}
$$

### 2.5.2.6.2 Two Phase Evaporation

Similarly to condensation, evaporation flow patterns are developed by J.R.Thome and his team mates. Furthermore, in this case some flow patterns are added. The flow pattern names are respectively, Slug (S), Slug + stratified wavy (SSW), Stratified wavy (SW),
Intermittent (I), Annular (A), Dryout (D) and Mist (M) flow [42]. Once more, the transition mass flow velocities designate the flow pattern conditions.
The zone is distinguished by the flow pattern as;
Slug zone
If $\mathrm{G}_{\text {wavy,xIA }}<\mathrm{G}$ and $\mathrm{G}_{\text {wavy }}>\mathrm{G}$
Slug+stratified wavy zone
if $\mathrm{G}_{\text {strat }}<\mathrm{G}<\mathrm{G}_{\text {wavy, } \mathrm{xIA}}$ and $\mathrm{x}<\mathrm{x}_{\text {IA }}$ and $\mathrm{G}_{\text {wavy }}>\mathrm{G}$
Stratified wavy zone
if $x \geq x_{I A}$ and $G_{\text {wavy }}>G$
Intermittent
if $\mathrm{G}>\mathrm{G}_{\text {wavy }}$ and $\mathrm{G}<\mathrm{G}_{\text {dryout }}$ and $\mathrm{x}<\mathrm{x}_{\text {IA }}$
Annular
if $\mathrm{G}>\mathrm{G}_{\text {wavy }}$ and $\mathrm{G}<\mathrm{G}_{\text {dryout }}$ and $\mathrm{x}>\mathrm{x}_{\text {IA }}$
Dryout
if $\mathrm{G}_{\text {mist }}>\mathrm{G}>\mathrm{G}_{\text {dryout }}$
Mist
if $\mathrm{G}>\mathrm{G}_{\text {mist }}$
Calculations are given below in respect to the calculation order. [43]

$$
\begin{align*}
& G_{\text {dry }, \text { out }}=\left[\begin{array}{c}

$$
\begin{gather*}
\left.x_{d e}=0.61 e^{\left[0.57-0.0058 W e_{V} 0^{0.38} F r_{V}\right.}{ }^{0.15}\left(\frac{\rho_{V}}{\rho_{L}}\right)^{-0.09}\left(\frac{q}{q_{c r i t}}\right)^{0.27}\right]  \tag{2.213}\\
h_{d r y o u t}=h_{t p}\left(x_{d i}\right)-\frac{x-x_{d i}}{x_{d e}-x_{d i}}\left[h_{t p}\left(x_{d i}\right)-h_{m i s t}\left(x_{d e}\right)\right] \tag{2.214}
\end{gather*}
$$

### 2.5.2.6.3 For single phase

Single phase calculations in evaporator and condenser are the same as given by the Gnielinski method [44]. In this case, refrigerant properties should be adjusted according to the refrigerant position either in superheated region or subcooled region. Calculations are given below.

If refrigerant is in subcooled region:
$\operatorname{Pr}_{\text {ref }} \neq \operatorname{Pr}_{\mathrm{L}}$ and $\mathrm{k}_{\text {ref }} \neq \mathrm{k}_{\mathrm{L}}$
If Refrigerant is in superheated region:
$\operatorname{Pr}_{\text {ref }}=\operatorname{Pr}_{V}$ and $\mathrm{k}_{\mathrm{ref}}=\mathrm{k}_{\mathrm{V}}$

$$
\begin{gather*}
h_{s p}=\frac{\left(R e_{\text {Din }}-1000\right) P r_{r e f}\left(\frac{f}{2}\right) k_{r e f}}{1+12.7 \sqrt{f / 2}\left(\operatorname{Pr}_{r e f}{ }^{0.67}-1\right) d_{i n}}  \tag{2.215}\\
f=\left[1.58 \ln \left(R e_{\text {Din }}\right)-3.28\right]^{-2} \tag{2.216}
\end{gather*}
$$

### 2.5.2.7 Refrigerant side pressure drop correlations

Refrigerant side pressure drop calculations are divided into three parts, frictional, acceleration and gravitational [6]. Frictional part is the most dominant part in calculations. While gravitational part is for change at elevation in heat exchanger, gravity effect is more dominant in low quality.

$$
\begin{equation*}
\Delta P_{\text {ref }}=\Delta P_{\text {fric }}+\Delta P_{\text {accel }}+\Delta P_{\text {grav }} \tag{2.217}
\end{equation*}
$$

### 2.5.2.7.1 Accelerational pressure drop

Accelerational pressure drop calculations are based on the inlet and outlet conditions in tube. Because of that, at single phase region, subcooled and superheated area momentum term is always positive, which means pressure increasing.

## For single phase

$$
\begin{equation*}
\Delta P_{\text {accel }}=G_{\text {ref }}^{2}\left(\frac{1}{\rho_{\text {ref }, \text { in }}}-\frac{1}{\rho_{\text {ref,out }}}\right) \tag{2.218}
\end{equation*}
$$

## For two phase

$$
\begin{equation*}
\Delta \mathrm{P}_{\mathrm{accel}}=\mathrm{G}_{\mathrm{ref}}{ }^{2}\left(\frac{\mathrm{x}^{2}}{\alpha \rho_{\mathrm{V}}}+\frac{(1-\mathrm{x})^{2}}{(1-\alpha) \rho_{\mathrm{L}}}\right) \tag{2.219}
\end{equation*}
$$

For void fraction calculations, usually Zivi's [45] formula is being used.

$$
\begin{equation*}
\alpha=\frac{1}{1+\frac{1-\mathrm{x}}{\mathrm{x}}\left(\frac{\rho_{\mathrm{V}}}{\rho_{\mathrm{L}}}\right)^{2 / 3}} \tag{2.220}
\end{equation*}
$$

### 2.5.2.7.2 Gravitational pressure drop

Gravitational pressure drop is for elevation difference for the refrigerant. Elevation difference occurs only in tube bends. [6]

$$
\begin{equation*}
\Delta P_{\text {grav }}=\rho_{\text {ref }} g L_{\text {seg }} \frac{H_{\text {coil }}}{L_{\text {coil }}} \tag{2.221}
\end{equation*}
$$

### 2.5.2.7.3 Frictional pressure drop

Frictional term is the most dominant section of the pressure drop calculations. As for single phase Ragazzi and Pederson approach is shown below, for two phase calculations Thome et al. [46] approach is described.

### 2.5.2.7.3.1 For single phase

Single phase calculations are given below, according to turbulent and laminar flow, also for vapor and liquid refrigerants.

If $\mathrm{Re}_{\mathrm{Din}} \leq 2300$

$$
\begin{equation*}
f_{r e f, V}=f_{r e f, L}=\frac{16}{R e_{d, i n}} \tag{2.222}
\end{equation*}
$$

If $100,000 \geq \operatorname{Re}_{\text {Din }} \geq 2300$
For vapor refrigerant

$$
\begin{equation*}
f_{r e f, V}=\frac{0.046}{\left(R e_{d, i n}\right)^{0.2}} \tag{2.223}
\end{equation*}
$$

For liquid refrigerant

$$
\begin{equation*}
f_{r e f, L}=\frac{0.079}{\left(R e_{d, i n}\right)^{0.25}} \tag{2.224}
\end{equation*}
$$

If $\operatorname{Re}_{\mathrm{Din}} \geq 100,000$

$$
\begin{equation*}
f_{\text {ref }, V}=f_{\text {ref }, L}=\frac{0.0032+0.221\left(R e_{d, i n}\right)^{-0.237}}{4} \tag{2.225}
\end{equation*}
$$

Frictional pressure-drop for vapor and liquid:

$$
\begin{align*}
& \Delta P_{f, L}=\frac{2 f_{L} G^{2} L}{d_{i} \rho_{r e f}}  \tag{2.226}\\
& \Delta P_{f, V}=\frac{2 f_{V} G^{2} L}{d_{i} \rho_{r e f}} \tag{2.227}
\end{align*}
$$

### 2.5.2.7.3.2 Two phase evaporation frictional pressure drop

For two phase calculations are similar to evaporation heat transfer coefficients. Again,
flow pattern method is used by Thome et al. Refrigerant flow positions are similar to evaporation heat transfer coefficients.

Annular flow

$$
\begin{gather*}
u_{V}=\frac{G}{\rho_{V}} \frac{x}{\varepsilon_{v v}}  \tag{2.228}\\
u_{L}=\frac{G}{\rho_{L}} \frac{1-x}{1-\varepsilon_{v v}}  \tag{2.229}\\
W e_{L}=\frac{\rho_{L} u_{L}^{2} d_{i}}{\sigma}  \tag{2.230}\\
f_{i, \text { anular }}=0.67\left[\frac{\delta}{d_{i}}\right]^{1.2}\left[\frac{\left(\rho_{L}-\rho_{V}\right) g \delta^{2}}{\sigma}\right]^{-0.4}\left(\frac{\mu_{V}}{\mu_{L}}\right)^{0.08}\left(W e_{L}\right)^{-0.034}  \tag{2.231}\\
\Delta P_{\text {annular }, f}=4 f_{i, \text { anular }}\left(\frac{L}{d_{i}}\right) \frac{\rho_{V} u_{V}^{2}}{2} \tag{2.232}
\end{gather*}
$$

Figure 2-14 Flow pattern map evaluated for R-22 (Source:[40])

Slug + Intermittent flow

$$
\begin{gather*}
\varepsilon_{h}=\left(1+\left(\frac{1-x}{x}\right)\left(\frac{\rho_{V}}{\rho_{L}}\right)\right)^{-1}  \tag{2.233}\\
\varepsilon_{r a}=\frac{x}{\rho_{v}}\left([1+0.12(1-x)]\left[\frac{x}{\rho_{v}}+\frac{1-x}{\rho_{L}}\right]+\frac{1.18(1-x)\left[g \sigma\left(\rho_{L}-\rho_{v}\right)\right]^{0.25}}{G \rho_{L}^{0.5}}\right)^{-1}  \tag{2.234}\\
\varepsilon_{v v}=\frac{\varepsilon_{h}-\varepsilon_{r a}}{\ln \left(\frac{\varepsilon_{h}}{\varepsilon_{r a}}\right)}  \tag{2.235}\\
\Delta P_{\text {slug+intermittent }, f}=\Delta P_{f, L}\left(1-\frac{\varepsilon_{v v}}{\varepsilon_{v v, x I A}}\right)^{0.25}+\Delta P_{\text {annular }}\left(\frac{\varepsilon_{v v}}{\varepsilon_{v v, I A}}\right)^{0.25} \tag{2.236}
\end{gather*}
$$

Stratified wavy flow

$$
\begin{gather*}
\theta_{d r y}^{*}=\frac{\theta_{d r y}}{2 \pi}  \tag{2.237}\\
R e_{G}=\frac{G x d_{i}}{\mu_{V} \varepsilon_{v v}}  \tag{2.238}\\
f_{t p, s t r a t i f i e d w a v y}=\theta_{d r y}^{*} \Delta P_{f, V}+\left(1-\theta_{d r y}^{*}\right) f_{i, \text { anular }} \tag{2.239}
\end{gather*}
$$

$$
\begin{equation*}
\Delta P_{\text {stratifiedwavy }, f}=4 f_{t p, \text { stratifiedwavy }}\left(\frac{L}{d_{i}}\right) \frac{\rho_{G} u_{G}{ }^{2}}{2} \tag{2.240}
\end{equation*}
$$

Slug + Stratified wavy flow

$$
\begin{equation*}
\Delta P_{\text {slug }+ \text { stratifiedwavy }, f}=\Delta P_{f, L}\left(1-\frac{\varepsilon_{v v}}{\varepsilon_{v v, I A}}\right)^{0.25}+\Delta P_{\text {stratifiedwavy,f }}\left(\frac{\varepsilon_{v v}}{\varepsilon_{v v, I A}}\right)^{0.25} \tag{2.241}
\end{equation*}
$$

Mist flow

$$
\begin{gather*}
\varepsilon_{H}=\frac{1}{1+\frac{1-x}{x} \frac{\rho_{V}}{\rho_{L}}}  \tag{2.242}\\
\mu_{m}=x \mu_{V}+(1-x) \mu_{L}  \tag{2.243}\\
R e_{m}=\frac{G d_{i}}{\mu_{m}} \tag{2.244}
\end{gather*}
$$

$$
\begin{gather*}
\rho_{m}=\rho_{L}\left(1-\varepsilon_{H}\right)+\rho_{g} \varepsilon_{H}  \tag{2.245}\\
\Delta P_{m i s t, f}=2 \Delta P_{s p, f, m}\left(\frac{L}{d_{i}}\right) \frac{G^{2}}{\rho_{m}} \tag{2.246}
\end{gather*}
$$

Dryout Flow

$$
\begin{gather*}
\mu_{m, x d e}=x_{d e} \mu_{V}+\left(1-x_{d e}\right) \mu_{L}  \tag{2.247}\\
R e_{H}=\frac{G d_{i}}{\mu_{m, x d e}}  \tag{2.248}\\
\Delta P_{m i s t, f *}=2 \Delta P_{s p, f, m, x d e}\left(\frac{L}{d_{i}}\right) \frac{G^{2}}{\rho_{m}}  \tag{2.249}\\
u_{V}=\frac{G}{\rho_{V}} \frac{x_{d i}}{\varepsilon_{v v}}  \tag{2.250}\\
u_{L}=\frac{G}{\rho_{L}} \frac{1-x_{d i}}{1-\varepsilon_{v v}}  \tag{2.251}\\
f_{i, \text { anular* }}=0.67\left[\frac{\delta}{d_{i}}\right]^{1.2}\left[\frac{\left(\rho_{L}-\rho_{V}\right) g \delta^{2}}{\sigma}\right]^{-0.4}\left(\frac{\mu_{V}}{\mu_{L}}\right)^{0.08}\left(W e_{L, x d i}\right)^{-0.034}  \tag{2.252}\\
\Delta P_{\text {annular }, f *}=4 f_{i, a n u l a r *}\left(\frac{L}{d_{i}}\right) \frac{\rho_{G} u_{G}^{2}}{2}  \tag{2.253}\\
\Delta P_{\text {dryout }, f}^{2}=\Delta P_{\text {annular }, f *}-\frac{x-x_{d i}}{x_{d e}-x_{d i}}\left(\Delta P_{\text {annular }, f *}-\Delta P_{m i s t, f *}\right) \tag{2.254}
\end{gather*}
$$

Stratified flow

$$
\begin{gather*}
\theta_{\text {strat }}{ }^{*}=\frac{\theta_{\text {strat }}}{2 \pi}  \tag{2.256}\\
f_{\text {tp,stratified }}=\theta_{\text {strat }}{ }^{*} \Delta P_{\text {sp, } f, V}+\left(1-\theta_{\text {strat }}{ }^{*}\right) f_{i, \text { anular }} \tag{2.257}
\end{gather*}
$$

$$
\begin{gather*}
u_{V}=\frac{G}{\rho_{V}} \frac{x}{\varepsilon_{v v}}  \tag{2.258}\\
\Delta P_{\text {stratified, } 1}=4 f_{t p, \text { stratified }}\left(\frac{L}{d_{i}}\right) \frac{\rho_{V} u_{V}^{2}}{2} \tag{2.259}
\end{gather*}
$$

If $x \geq x_{\text {IA }}$

$$
\begin{equation*}
\Delta P_{\text {stratified }, f}=\Delta P_{\text {stratified }, 1} \tag{2.260}
\end{equation*}
$$

If $\mathrm{x}<\mathrm{x}_{\text {IA }}$

$$
\begin{equation*}
\Delta P_{\text {stratified }, f}=\Delta P_{f, L}\left(1-\frac{\varepsilon_{v v}}{\varepsilon_{v v, I A}}\right)^{0.25}+\Delta P_{\text {stratified }, 1}\left(\frac{\varepsilon_{v v}}{\varepsilon_{v v, I A}}\right)^{0.25} \tag{2.261}
\end{equation*}
$$

According to Thome et al., studies range of application for evaporation, condensation heat transfer and frictional correlations are shown below:
$3.1<\mathrm{d}_{\mathrm{in}}<21.4$
$0.02<\mathrm{p}_{\mathrm{r}}<0.8$
$76<(\mathrm{We} / \mathrm{Fr})_{\mathrm{L}}<884$

Applicable refrigerants: Ammonia, R-11, R-12, R-22, R-32, R-113, R-123, R-125, R-134a, R236ea, R-32/R-125 near azeotrope, R-402A, R-404A, R-407C, R-410A, $\mathrm{R}-502$, propane, n -butane, iso-butane and propylene.

### 2.5.2.7.3.3 Two phase condensation frictional pressure drop

Condensation pressure drop calculations, are shown below as Souza et al. [47] correlations. This method is based on the calculation of the liquid refrigerant pressure drop correlated according to the two-phase section.

$$
\begin{equation*}
\Delta P_{f}=\Delta P_{f, L} \emptyset_{l i q}{ }^{2} \tag{2.262}
\end{equation*}
$$

Where $\Delta P_{f}$ is the frictional pressure drop in liquid phase and $\emptyset_{\text {liq }}{ }^{2}$ is the two phase correction factor.

$$
\begin{equation*}
\emptyset_{l i q}{ }^{2}=1.376+\frac{C_{1}}{X_{t t}^{C_{2}}} \tag{2.263}
\end{equation*}
$$

Where

If $\mathrm{Fr}_{\mathrm{L}} \geq 0.7$

$$
\begin{align*}
& C_{1}=7.242  \tag{2.264}\\
& C_{2}=1.655 \tag{2.265}
\end{align*}
$$

If $\mathrm{Fr}_{\mathrm{L}}<0.7$

$$
\begin{gather*}
C_{1}=4.172+5.48 F r_{L}-1.564 F r_{L}^{2}  \tag{2.266}\\
C_{2}=1.773-0.169 F r_{L}  \tag{2.267}\\
F r_{L}=\frac{G_{r e f}{ }^{2}}{\rho_{L} g d_{i}}  \tag{2.268}\\
X_{t t}=\left(\frac{\rho_{V}}{\rho_{L}}\right)^{0.5}\left(\frac{\mu_{V}}{\mu_{L}}\right)^{0.125}\left(\frac{1-x_{r e f}}{x_{r e f}}\right)^{0.875} \tag{2.269}
\end{gather*}
$$

Correlation is valid for $\mathrm{x}_{\text {ref }} \geq 0.17$. If $\mathrm{x}_{\text {ref }}<0.17$ interpolation between liquid and twophase correlations should be used.

### 2.5.2.8 Heat transfer area

The common equations which are used to calculate heat transfer surface are are listed below according to wavy and plain fins. [48]

Fin spacing

$$
\begin{equation*}
F_{s}=F_{p}-t_{f i n} \tag{2.270}
\end{equation*}
$$

Number of fins

$$
\begin{equation*}
N_{f}=\frac{L_{c o i l}-F_{s}}{t_{f i n}+F_{s}} \tag{2.271}
\end{equation*}
$$

Coil height

$$
\begin{equation*}
H_{c o i l}=P_{t} N_{t} \tag{2.272}
\end{equation*}
$$

Face area

$$
\begin{equation*}
A_{\text {face }}=H_{\text {coil }} L_{\text {coil }} \tag{2.273}
\end{equation*}
$$

Outside tube area

$$
\begin{equation*}
A_{p}=\left(\pi d_{o} L_{\text {coil }}-N_{f} t_{f i n}\right) N N_{t} \tag{2.274}
\end{equation*}
$$

Total surface area

$$
\begin{equation*}
A_{o}=A_{f}+A_{p} \tag{2.275}
\end{equation*}
$$

Plain fin area

$$
\begin{equation*}
A_{f}=2\left[W_{\text {coil }} H_{\text {coil }}-\left(\frac{\pi d_{o}^{2}}{4}\right) N_{t}\right] N_{f} L_{\text {coil }}+2 H_{\text {coil }} t_{\text {fin }} N_{f} L_{\text {coil }} \tag{2.276}
\end{equation*}
$$

Wavy fin area

$$
\begin{gather*}
\sec \theta=\frac{\sqrt{x_{f}^{2}+P_{d}^{2}}}{x_{f}}  \tag{2.277}\\
A_{f}=2\left(H_{c o i l} X_{l} N \sec \theta-N_{t} N \pi d_{o}^{2} / 4\right) N_{f i n} \tag{2.278}
\end{gather*}
$$

Minimum flow area is calculated based on the arrangement type such as
For staggered arrangement

$$
\begin{gather*}
2 a=\left(P_{t}-d_{o}\right)-\left(D_{c}-d_{o}\right) t_{f i n} N_{f}  \tag{2.279}\\
2 b=2\left(\sqrt{\left[\left(\frac{P_{t}}{2}\right)^{2}+X_{l}^{2}\right]}-d_{o}-\left(D_{c}-d_{o}\right) t_{f i n} N_{f}\right)  \tag{2.280}\\
A_{o}=\left[\left(\frac{H_{\text {coil }}}{P_{t}}-1\right) c+\left(P_{t}-d_{o}\right)-\left(d_{c}-d_{o}\right) t_{f i n} N_{f}\right] L_{\text {coil }} \tag{2.281}
\end{gather*}
$$

If $2 a<2 b$ then $c=2 b$ else $c=2 a$

For inline arrangement

$$
\begin{equation*}
A_{o}=\left[\left(P_{t}-d_{o}\right) L_{c o i l}-\left(d_{c}-d_{o}\right) t_{f i n} N_{f} L_{c o i l}\right] \frac{H_{c o i l}}{P_{t}} \tag{2.282}
\end{equation*}
$$

## CHAPTER 3

## COMPRESSOR CYCLE ALGORITHM

Previously, equipment in vapor compression refrigeration cycle were introduced. Furthermore, the equations and correlations of heat transfer and pressure drop calculations were given for all the equipment in distinct flow types and cases. In this section, an algorithm is proposed which uses all the discussed equations and correlations to connect all the equipment in the refrigeration cycle and documents the effect of all equipment on the cycle as a real time simulation.

In order to specify specific application, the following information is required for the program:

- Outdoor temperature \& relative humidity ( RH )
- Indoor temperature \& RH
- Air flow over condenser and evaporator
- Air flow distribution around the condenser and evaporator copper tubes
- Condenser and evaporator circuit arrangement
- Refrigerant type
- Compressor model
- Compressor sub-cooling and superheat point
- Suction and discharge copper tube diameter, length and settlement
- Compressor cycle mode, cooling or heating

Then, in order for the program to begin iterations 'calculation button' should be clicked. Algorithm of the program is given in the figure 3.1. Simulation program first calculates the compressor mass flow. Then, it calculates the discharge tube outlet condensation temperature to use in condenser inlet. Condenser calculations can start with the inlet condensation temperature. In condenser, pressure drop, heat transfer and outlet temperature of refrigerant and air are calculated in each segment. Then, if condenser outlet subcooling value is the same with compressor subcooling value which is a user input, simulation program continues with the next step to calculate liquid line pressure drop and refrigerant mass; otherwise, it iterates
until compressor condensation temperature error decreases to $1^{\circ} \mathrm{C}$. After liquid line calculations, program continues with evaporator calculations, which are similar to condenser side. Then, program calculates the suction line outlet evaporation temperature and superheat temperature. If these values are the same same with compressor inlet values calculations, the calculations are stopped and the results are written; otherwise the algorithm iterates to reduce compressor condensation and evaporation temperature until the error decreases to $1^{\circ} \mathrm{C}$.

Overall, the algorithm uses heat transfer and pressure drop equations and correlations in order to calculate all properties for the entire cycle. The user can also decide to the number of segments the problem to be divided. However, it should be noted that the number of segments increases the accuracy but also computational time. Furthermore, the algorithm calculates the values and iterates until all the properties in the cycle are in accord.

Figure 3-1 Software simulation algorithm

## CHAPTER 4

## HEAT EXCHANGER SIMULATION RESULTS

Here the results of the developed algorithm is compared with Friterm heat exchanger simulation program. Unfortunately, the cost of experimental study was a constraint so is the lack of experimental data in the literature. Therefore, it is decided to validate the algorithm with commercially used software of Friterm heat exchanger simulation program. The same problem is defined in both software defined as in Tables 4-1 and 4-2. Then, capacity and pressure drop values supplied by the softwares are compared. Main difference between the developed algorithm and Friterm software is related with the circuitry of the exhangers and air flow distribution. Friterm software [49] is not capable of including the circuitry information and it uses common circuitry algorithm of $Z$ shape. In addition, it does not enable user to define air flow distribution and uses uniform air flow distribution in the software. However, developed software enables for user to include the circuitry of heat exchangers and include how the air flow distributed over the exchangers. Especially, if there is a computational fluid dynamics simulations at hand that can be incorporated to enhance to accuracy of the results.

Table 4-1 Condenser calculation comparation between this study and Friterm software (Source: [49])

## CHAPTER 5

## CONCLUSION

In this study, basic equipment of water-cooled and air-cooled vapor compression cycle were introduced. The equipment was specified and the advantages and disadvantages of specific type of equipment were discusses such as piston, screw and rotary compressors. The heat transfer and pressure drop equations were given for finned tube heat exchangers specifically for condensers and evaporators. The correlations were specified whether the flow is single phase or two phase, if two phase what is the characteristics of the flow (slug, intermittent or annular zone) and Reynolds number. The mathematical calculation model of zone-by-zone, tube-by-tube and segment by segment were specified. Each method calculates the correlations for defined zones, tubes or segments. Segment by segment method is selected for the developed algorithm because it is the most accurate method if the segment number is increased. In addition, its results can be adopted that if the segment number is the same with the number of tubes then the results became the same with the tube by tube method. After introducing the correlations and deciding on the mathematical calculation method, difference between e-Ntu and LMTD are discussed. Then, the compressor polynomials were documented. The algorithm of the developed software was also discussed where not only a specific heat exchanger calculated by the software but the all the properties for all components are calculated simultaneously. Therefore, the designer should not use several selections software packages, one for condenser, another for evaporator and so on. In addition, as the design parameters varied the input values for each program should be altered and working conditions should be satisfied by the user. However, developed software eliminates this confusion by enabling all the simulations to be run simultaneously and satisfy working conditions automatically. Then in order to validate the accuracy of the developed software, the results of a commercially available heat exchanger selection software was used. The results of the sample case showed that the results of the developed software is acceptable.
